112		EXECUTIVE SUMMARY
113		
114	•	This report covers New Mexico Fish and Wildlife Conservation Office (NMFWCO)
115		Rio Grande Silvery Minnow (RGSM) augmentation activities for the 2023 cohort.
116	•	Spring runoff in early 2023 was high, resulting in a request of 60,000 hatchery-reared
117	;	age-0 fish to supplement the wild 2023 cohort.
118	•	The color of visible implant elastomer (VIE) tags used for identifying RGSM released
119		in 2023 was red right dorsal for all facilities.
120	•	Based on September 2023 population monitoring, the Middle Rio Grande valley had
121	2	> 1.0 RGSM per $100m^2$ but <50% occupied sites in the San Acacia Reach, leading to
122	;	a final request of 46,000 RGSM for release in the San Acacia Reach.
123	•	46,484 hatchery-reared age-0 Rio Grande Silvery Minnows were released in
124		November and December 2023. All were given a red right VIE tag prior to release.
125	•	Fish from the Los Lunas Silvery Minnow Refugium did not meet minimum condition
126		factor requirements and were held back to grow out to a larger size.
127	•	120 VIE-marked fish were recaptured between January and December 2023, all from
128		the 2023 cohort. The majority of recaptures $(N = 85)$ were during fish rescue
129	;	activities.
130	•	A pilot mark-recapture study continued in 2023 to determine the feasibility of robust-
131		design mark recapture to estimate monthly survival, movement, and capture
132		efficiency of Rio Grande Silvery Minnow. A total of 3,983 Rio Grande Silvery
133		Minnow were captured in 2023, compared to 7 in 2022.

#### **INTRODUCTION**

In 2001, the Rio Grande Silvery Minnow Hybognathus amarus (RGSM) Augmentation 138 Plan (USFWS 2001) was developed to help prevent extinction of the species by increasing their 139 numbers in the Rio Grande. Since that time, >3 million hatchery reared RGSM have been 140 released into the Middle Rio Grande (MRG), New Mexico. The initial goal of the RGSM 141 Augmentation Plan was to produce 500,000 RGSM each year for release based on the expected 142 capacities of propagation facilities, along with current population status and suggestions from 143 geneticists. Stocking and monitoring efforts were focused on the Angostura Reach (also known 144 as the Albuquerque Reach) where catch rates of wild RGSM were extremely low and the 145 expected benefit of augmentation could be maximized (Remshardt and Davenport 2003). 146 However, actual production has been limited to 300,000 or less per year since 2010 and stocking 147 has occurred in the Angostura, Isleta, and San Acacia Reaches when needed based on autumn 148 abundance. 149

Varying numbers of RGSM have been released in the MRG each year ranging from 0 to 150 151 400,000 depending on river conditions. Between 2002 and 2004, 100,000 to 200,000 RGSM were released annually in the Angostura Reach. Annual releases were based on calculations to 152 reach target densities of 1 fish/100m<sup>2</sup>. Starting in 2005, augmentation expanded to include the 153 Isleta and San Acacia Reaches. In addition to augmentation and other conservation measures 154 155 such as habitat improvement, improved spring runoff and habitat conditions improved survival in 2005 allowing RGSM to increase in abundance. Between 2005 and 2007, 100,000 to 400,000 156 157 RGSM were released annually throughout all reaches (Remshardt 2008). In 2008, USFWS began implementing a revised 5-year RGSM Augmentation Plan, in which the Angostura Reach 158 159 was purposely not stocked in order to evaluate the effect of hatchery augmentation. Favorable spring run-off conditions for recruitment beginning in 2008 meant that no augmentation was 160 needed that year; however, the number of RGSM stocked during the low spring run-off years of 161 2012 to 2014 was near maximum capacity of production facilities. Following increased 162 recruitment in 2015 and 2016, the 2017 cohort of RGSM was one of the strongest observed in 163 the MRG. Declines in abundance during the drought years of 2020-2021 lead to an increase in 164 the numbers of hatchery fish released. 165

This report summarizes augmentation planning and release activities during the 2023 166 calendar year. This effort addresses management needs identified in Item A.2.2 of the Middle 167 168 Rio Grande Endangered Species Collaborative Program (MRGESCP), Tasks 8b and 8d of the Rio Grande Silvery Minnow Recovery Plan, 1st Revision, (Recovery Plan; USFWS 2010), and 169 Reasonable and Prudent Measure #5 of the Biological Opinion (USFWS 2016). These tasks 170 include development and refinement of augmentation protocols for use in the Middle Rio Grande 171 (Task 8b) and annual monitoring of augmented populations is identified as a needed task (Task 172 8d). 173

A recovery outcome of a self-sustaining population of RGSM in the Middle Rio Grande 174 requires numerous actions outlined in the Recovery Plan. The goal of augmentation is to support 175 the wild population of RGSM in the Middle Rio Grande by bolstering resistance and resilience to 176 disturbance and other environmental stressors (Archdeacon et al. 2023b), until such time the 177 population is self-sustaining. Augmentation accomplishes this goal by improving the abundance 178 and distribution of RGSM in the Middle Rio Grande, thereby improving the demographic 179 resilience of the species. Long-term objectives of this project are to promote the recovery of 180 181 RGSM through 1) augmenting populations within the MRG with hatchery-raised fish as necessary; and 2) evaluating stocking efforts and methods to improve effectiveness of these 182 actions. 183

Specific objectives of augmentation in 2023 were to implement the 5-year augmentation and stocking protocol (Archdeacon 2022), including assisting with spring production estimates, collection of eggs for broodstock and refuge populations, and calculating the number of RGSM necessary to meet target densities of 1 fish/100m<sup>2</sup> within each reach.

188 189

#### **METHODS**

190 *Study Area* 

This investigation concentrated on areas within the Angostura, Isleta, and San Acacia reaches (Figure 1). The Angostura Reach (~40 mi) extends from Angostura Diversion Dam (River Mile [RM] 209.7) to Isleta Diversion Dam (RM 169.3) and includes the cities of Bernalillo, Corrales, and Albuquerque. The Isleta Reach (~54 km) extends from Isleta Diversion Dam to San Acacia Diversion Dam, and includes the southern portion of Isleta Pueblo, cities of Bosque Farms, Valencia, Los Lunas, Belen, and smaller villages such as La Joya, and Bernardo,

along with Sevilleta National Wildlife Refuge, all within Bernalillo, Valencia, and Socorro 197 Counties. The San Acacia Reach (~76 km) extends from San Acacia Diversion Dam to the 198 199 headwaters of Elephant Butte Reservoir (the exact location of the lower boundary varies depending upon reservoir water-surface elevation). This reach is relatively remote, including 200 only the city of Socorro and villages of San Acacia, Lemitar, Escondida, and San Antonio along 201 with Bosque del Apache National Wildlife Refuge, within Socorro and Sierra Counties. 202 203 Spring Estimation of Production Needs 204 Hatchery facilities must plan for spring spawning by May of each year and require 205 estimates of numbers of fish needed for autumn augmentation. Spring planning numbers are 206 estimated from the April 1 streamflow forecast of each year and are incorporated in a regression 207 model that is updated with new data each year. The forecasted 50% exceedance streamflow, in 208 thousands of acre-feet (KAF), March through July at the Otowi gage (available at 209 https://www.nrcs.usda.gov/wps/portal/wcc/home/snowClimateMonitoring/snowpack/basinDataR 210 eports/) is used to predict the actual numbers of fish released in the autumn (described below). 211 212 As more years are included, the model will be able to incorporate other parameters, including

existing numbers of fish from previous cohorts, which should improve both the precision and

accuracy of predictions. A generalized linear regression model was used to relate actual

numbers of fish needed to the spring forecast. As a conservative measure, the upper 95%

confidence interval is used for the spring estimation of augmentation needs.

217

## 218 Collection of Wild-caught Eggs for Broodstock and Refuge Population

Rio Grande Silvery Minnow spawning typically occurs in May and June (Archdeacon et al. 2023a). Rio Grande Silvery Minnow release semi-buoyant, non-adhesive eggs directly into the water column (Platania and Altenbach 1999). During times of high spawning activity and lower discharge, eggs can be easily collected from the river (Altenbach et al. 2000). These eggs may be transported to rearing facilities to serve as broodstock or a refuge population, or returned to the river in years when large numbers are collected (Archdeacon et al. 2023b). During highflow years, larvae or juveniles are collected during summer and autumn months.

228Following the revised RGSM Augmentation Plan 2018-2022 (Archdeacon 2022),229augmentation efforts were focused on all three reaches (Angostura, Isleta, and San Acacia) in2012022. September catch-rates (e.g., catch-per-unit-effort; fish/100m <sup>2</sup> ) from preliminary211population monitoring results (R. Dudley, personal communication) were used as criteria to222determine the need for augmentation and the number of fish required. If the entire reach average233was >1.0 fish/100m <sup>2</sup> and >50% of monitoring sites were occupied, then augmentation was not234required. If either of the criteria were not met, augmentation occurred and the total number of235fish for the reach was calculated as given below (Archdeacon 2022). Surface area between sites236was estimated from aerial imagery and average wetted conditions.237The number of fish to augment for each site (S <sub>i</sub> ) was determined using the following239formula:240 $S_i = (C_t - C_o) x$ (total estimated area $m^2$ between $S_i$ and $S_{i+1}$ )241where; $C_t =$ Target catch rate at each site, or 1 fish / 100 m <sup>2</sup> ,242 $C_o$ = Observed catch rate at site <i>i</i> in September243 $S_i = Number of fish to release at site i244S_i + 1 = Next downstream site of site i245Once the required number of fish per reach was spread among at least three release246locations per reach.247betwein fish of all austored (1 mm) standard and total length of at248site and the output of sich or clease at site i249Fish Condition Factor$	227	Autumn Estimation of Augmentation Needs
2022. September catch-rates (e.g., catch-per-unit-effort; fish/100m²) from preliminarypopulation monitoring results (R. Dudley, personal communication) were used as criteria todetermine the need for augmentation and the number of fish required. If the entire reach averagewas >1.0 fish/100m² and >50% of monitoring sites were occupied, then augmentation was notrequired. If either of the criteria were not met, augmentation occurred and the total number offish for the reach was calculated as given below (Archdeacon 2022). Surface area between siteswas estimated from aerial imagery and average wetted conditions.required. If either of fish to augment for each site (Si) was determined using the followingformula:formula:Si = (Ct - Co) x (total estimated area m² between Si and Si + 1)where;Ct = Target catch rate at each site, or 1 fish / 100 m²,Ca = Observed catch rate at site i in Septembersi = Number of fish to release at site iSi = Number of fish per site was determined, it was summed perreach. The total number of fish per site was determined, it was summed perreach. The total number of fish per reach was spread among at least three releaselocations per reach.We weighed (0.01 g) and measured (1 mm) standard and total length of atleast 100 haphazardly selected (and assumed representative) fish from eachfacility. We calculated Fulton's condition factor (Ka; see Froese 2006) for thesefish; augmentation guidelines are that fish should be 45 mm TL and have acondition factor of Ka > 0.80 to improve survival and reproduction post-release	228	Following the revised RGSM Augmentation Plan 2018-2022 (Archdeacon 2022),
231population monitoring results (R. Dudley, personal communication) were used as criteria to232determine the need for augmentation and the number of fish required. If the entire reach average233was >1.0 fish/100m <sup>2</sup> and >50% of monitoring sites were occupied, then augmentation was not234required. If either of the criteria were not met, augmentation occurred and the total number of235fish for the reach was calculated as given below (Archdeacon 2022). Surface area between sites236was estimated from aerial imagery and average wetted conditions.237The number of fish to augment for each site (Si) was determined using the following239formula:240 $S_i = (C_I - C_O) x$ (total estimated area $m^2$ between $S_i$ and $S_i + I$ )241where; $C_t$ = Target catch rate at each site, or 1 fish / 100 m <sup>2</sup> ,242 $C_o$ = Observed catch rate at site i in September243 $S_i = Number$ of fish to release at site i244 $S_i + 1 = Next$ downstream site of site i245Once the required number of fish per reach was spread among at least three release246locations per reach.247We weighed (0.01 g) and measured (1 mm) standard and total length of at248least 100 haphazardly selected (and assumed representative) fish from each249facility. 256 Tagging

Tagging followed the standard operating procedures for tagging Rio Grande Silvery
Minnow with VIE tags. For fish released in 2023, tags were placed in the right dorsal position.
All facilities used red VIE tags for marking.

260

261 Fish Releases

Rio Grande Silvery Minnow are loaded in large transport tanks at the hatcheries and are 262 transported to a site where trucks can get close to flowing water. River water was used to temper 263 the tanks to within 1°C of the river water. The RGSM are then released directly from the trucks 264 into areas of low or zero velocity water at stocking sites. If the transport trucks are unable to get 265 access to the river, RGSM are loaded into smaller transport tanks in the back of off-road vehicles 266 following transport protocols developed for RGSM fish rescue along with the tempered water, 267 and then driven to the river and released into low velocity habitats. Specific timing and release 268 sites are chosen to avoid releasing fish directly at standard monitoring sites. Up to three release 269 locations were chosen for each reach, based on the areas with the lowest densities and river 270 271 access (Archdeacon 2022).

272

### 273 *Recapture Data from Other Researchers*

Recapture data collected from other researchers continue to provide valuable information 274 275 on movement and survival of VIE marked fish. Included in this year's summary are collections from standard population monitoring work for RGSM conducted by ASIR (American Southwest 276 Ichthyological Researchers, LLC), data from NMFWCO RGSM fish rescue projects, the U.S. 277 Bureau of Reclamation, and the University of New Mexico (UNM) genetic monitoring. These 278 279 researchers were asked to provide recapture information on VIE-marked RGSM. These projects have varying objectives and methods, but a summary of recaptures can provide an overall view 280 of RGSM movement and retention in release areas. 281

282

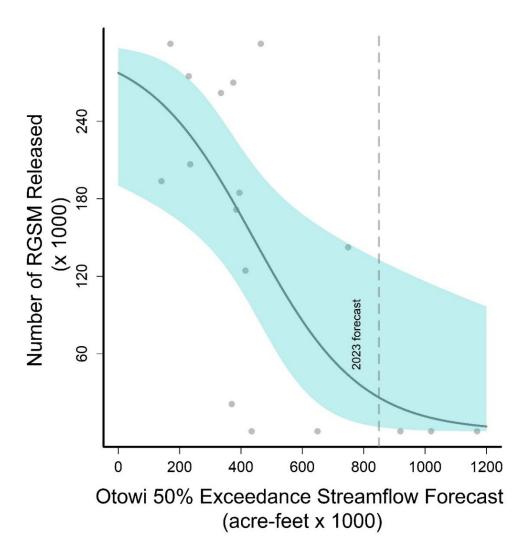

### RESULTS

### 285 Spring Estimation of Production Needs

The forecasted 50% exceedance flow at Otowi for March through July was 850 KAF

- (Figure 1). This resulted in a request for 60,000 age-0 Rio Grande Silvery Minnow to be
- spawned and reared for augmentation in autumn (Figure 1).

289

290

Figure 1- Association between numbers of Rio Grande Silvery Minnow released in autumn and

the forecasted spring-summer streamflow at the Otowi gage in the Rio Grande, New Mexico.

293 The gray area represents the 95% confidence interval for numbers of hatchery fish actually

required in each year. The model is updated yearly. The dashed line represents the forecasted

2023 spring flows and is used to estimate hatchery production of age-0 RGSM in May.

# 296 Collection of Wild-caught Eggs for Broodstock and Refuge Population

Due to high flows, the NMFWCO collected no RGSM eggs for broodstock during 2023. However, multiple collections of larvae and juveniles resulted in >5,000 RGSM transferred to the Albuquerque BioPark for rearing (Appendix A). These fish were treated for infections and reared to a size large enough to identify. After identification, some of these fish were transferred to SNARRC.

302

# 303 Estimation of Augmentation Needs

Based on September 2023 catch rates from the standard RGSM monitoring program

305 conducted by ASIR, all three reaches had CPUE > 1.0 fish 100 m<sup>-2</sup>, but the San Acacia Reach

had < 50% site occupancy < 1.0 (Table 1). The total fish requested was 46,000 to be released in

307 the San Acacia Reach.

- 308 Table 1- Rio Grande Silvery Minnow monitoring sites, approximate surface area (ha) between it
- and the next site downstream during baseflows, and observed CPUE in September 2023, in the
- 310 Middle Rio Grande, New Mexico. DD = Diversion Dam, NWR = National Wildlife Refuge,
- 311 RRWWTP = Rio Rancho Wastewater Treatment Plant, SM = San Marcial. \*No stocking was
- necessary because CPUE was > 1.0 fish 100 m<sup>-2</sup> and reach occupancy > 0.50.

314	Fish Condition Factor
315	Fish were weighed and measured 17 October (LLSMR), 18 October (BioPark), or 16
316	November 2023 (Southwestern ARRC). Fish from Southwestern ARRC averaged 54.8 mm TL
317	and had an average $K_{tl} = 0.90$ . Fish from the LLSMR averaged 48.2 mm TL and had an average
318	$K_{tl} = 0.74$ . However, fish from the LLSMR raised in the outdoor refugium had significantly
319	lower $K_{tl}$ of 0.70 compared to 0.78 for fish raised in the D-series tanks. Because these fish were
320	in poor condition both visibly and had $K_{tl} < 0.80$ , none were released.
321	
322	Tagging
323	Tagging was completed at Southwestern ARRC and the BioPark. All fish were given red
324	right VIE markings.
325	
326	Fish Releases
327	A total of 46,484 RGSM were released at one site in 2023 (Figure 2).
328	
329	Recapture Data from Other Researchers
330	A total of 120 VIE-marked fish were recaptured between January and December 2023, all
331	from the 2022 release cohort. The majority of recaptures ( $N = 85$ ) were during fish rescue
332	activities. The longest fish at large was 210 days.
333

#### DISCUSSION

Over the past decade, RGSM densities have varied from year to year. Beginning in 2015, 344 RGSM abundance began to increase through 2017. In 2017, high spring runoff led to high 345 densities of RGSM. However, after poor recruitment in 2018 and 2020-2022, the annual 346 numbers of fish needed for augmentation increased. The association between the spring 347 hydrograph and the density of RGSM detected the following October is well established 348 Yackulic et al. 2022). The spring 2023 estimate based on forecasted streamflow suggested no 349 fish would be needed in the autumn, but 60,000 were requested as minimum production. The 350 high spring runoff peak prevented large egg collections, but many larvae and juveniles were 351 collected when flows began to recede. Considerable drying in the San Acacia Reach resulted in 352 the need to stock fish, as <50% of the monitoring sites had RGSM present. There is still 353 considerable variability and uncertainty in autumn planning needs when average flows are 354 between approximately 50 and 80%, though the years 2010 and 2018 appear to be outliers. As 355 more data are collected, this relationship should become clearer, allowing for more precise 356 estimates of augmentation needs in spring. The variability in augmentation needs is linked to the 357 358 abundance of the previous years' cohort as well as spring runoff.

Fish from Southwestern ARRC and the BioPark were generally in good condition ( $K_{tl}$  < 0.80). Unfortunately, fish from LLSMR were in poor condition, particularly those raised in the refugium (see raw data). Approximately 30,000 RGSM were not released due to being too small but may be released in 2024 depending on their size. Future research should include studies on how body condition of hatchery fish influences survival and performance after release. Making these determinations will help guide and improve propagation practices.

Rio Grande Silvery Minnow exhibit an opportunistic life-history with high demographic 365 366 resilience (Winemiller 2005), with short generation times, high reproductive effort (Caldwell et 367 al. 2019), high mobility (Archdeacon et al. 2018, Platania et al. 2020), and a short lifespan (Horwitz et al. 2018). Having high demographic resilience allows the population to rebound 368 quickly after disturbance. Over the previous five years, populations increased in 2017, followed 369 370 by four years of extreme annual variability in spring runoff. Populations rebounded in 2019 after 371 poor runoff and recruitment conditions in 2018 (Archdeacon et al. 2020). Thus, continued augmentation will be necessary in some years if spring run-off continues to be low and below 372 average and no other options to improve recruitment exist. However, continued and heavy 373

374	hatchery augmentation to stave off extinction has eroded RGSM genetics (Osborne et al. 2024).
375	Further refinement of production, release, as well as refining release numbers may help improve
376	the effectiveness of augmentation but will not replace habitat and flow restoration.
377	
378	ACKNOWLEDGEMENTS
379	Thanks to the many individuals who contributed to this project in 2023 including Lyle
380	Thomas, and Paige Dunnum from NMFWCO, Ty Terry, Jesse Truijillo, and William Knight
381	from the Southwestern Native Aquatic Research and Recovery Center. The University of New
382	Mexico, U.S. Bureau of Reclamation, and American Southwest Ichthyological Researchers LLC
383	provided technical advice and/or support during various phases of the project. This work was
384	funded through and interagency agreement with the U.S. Bureau of Reclamation Area Office in
385	Albuquerque, New Mexico.

### 463 Introduction

464 The Rio Grande Silvery Minnow is a small-bodied minnow that currently only found in the middle Rio Grande in central New Mexico. The range of the Rio Grande Silvery Minnow 465 (Hybognathus amarus) has been severely reduced and it now inhabits only 5% of its historical 466 range, occurring from Cochiti Dam downstream to Elephant Butte Reservoir (Bestgen and 467 Platania 1991). This loss of habitat has been caused by fragmentation due to dams constructed 468 for water diversions, which has also led to modified flow regimes and periodic channel drying 469 during summer months. Due to this severe decline, the Rio Grande Silvery Minnow was listed as 470 endangered in 1994 (USFWS 1994) and since then has been the focus of regular monitoring, 471 augmentation, and relocation during dewatering (USFWS 2010). In order to evaluate recovery 472 efforts, catch per unit effort (CPUE) is used as a metric as part of both the Rio Grande Silvery 473 Minnow Recovery Plan and Annual Augmentation Plan. 474

In support of improving the knowledge of the biology and ecology of Rio Grande Silvery Minnow, the New Mexico FWCO will work to improve the reliability of the CPUE metric. Several reviews of the long-term population monitoring program (e.g., Dudley et al. 2022) have recommended determining additional studies on the relationship between CPUE and abundance and developing correction factors to account for variable capture efficiencies among sites, years, and discharges (Hubert et al. 2016; Noon et al. 2017) improve the reliability of CPUE.

481 Capture-recapture is the gold standard in wildlife and fisheries studies for making inferences about demographic rates and overall abundance. While it is possible to estimate these 482 quantities without marking individuals, approaches that rely on unmarked fish are less precise 483 and less robust to violations of assumptions. For managers, the costs of imprecise estimates are a 484 485 poorer understanding of the drivers of population dynamics and less clarity regarding the 486 appropriate management responses. In recent years, modelling approaches have been developed to integrate intensive capture-recapture data collected over limited spatial scales and temporal 487 scales with more extensive, but less informative data (e.g., catch per unit effort data) to reach 488 robust inferences that build on the relative strengths on these two data types. Survival and 489 abundance estimate from RGSM capture-recapture would be invaluable for evaluating estimates 490 from models based on cruder data and would be integrated to improve our overall understanding 491

492 of RGSM demography and the impacts of various management actions on RGSM population493 dynamics.

494 *Objectives* 

The overarching objectives of this mark-recapture study is to estimate abundance of Rio 495 Grande Silvery Minnow within a small section of the MRG, estimating and accounting for 496 survival between sampling periods, immigration and emigration between sampling periods, and 497 capture efficiency. After sampling in multiple areas and years, we plan to synthesize results to 498 improve the utility of CPUE, which can be collected on a much larger spatial scale with less 499 effort. We determined that an initial pilot study would be beneficial to determine the feasibility 500 of initial study design and expected recapture rates. Full methodology will be developed after 501 this initial study and yearly review. Here, we examined sub-reach lengths and number of hauls 502 that would be reasonable to sample to determine expected capture and recapture rates. These 503 may need to be adjusted during years of high abundance. In years of low abundance of RGSM, 504 other species may be marked (i.e. flathead chub [Platygobio gracilis] and longnose dace 505 [*Rhinichthys cataractae*]). Visible implant elastomer (VIE) tags will be used to mark RGSM and 506 507 surrogate species greater than 30 mm standard length (SL), the color and placement of the tag indicating the time period and sub-reach in which it was caught. Thus, both capture history and 508 509 movement among sub-reaches can be determined and used to estimate population size, capture efficiency of seines, monthly survival, and to a limited extent, movement. 510

511

#### 512 Methods

For the initial pilot study, a 1.6 km portion of the San Acacia reach was chosen and 513 divided into four equal-length sections of 400 m (Figure 1). The sampling location was chosen 514 515 arbitrarily with the intention of having relatively more RGSM present for capture because it has not experienced river drying in at least the past two decades (Archdeacon and Reale, 2020) and 516 had a variety of mesohabitats present. We conducted sampling three times, two weeks apart, 517 covering a total sampling period of five weeks. Sampling began on September 11 and concluded 518 October 12. On the first day, sub-reaches 1 and 2 were sampled by conducting 10 seine hauls 519 per 100 m of stream length, totaling 40 seine hauls per sub-reach. We employed a seine (3.0 x 520 1.0 m, mesh size = 3.2 mm) and varied the habitat and length evaluated as much as possible. On 521 the second day, sub-reaches 3 and 4 were sampled with the same methodology. In 2023, RGSM 522

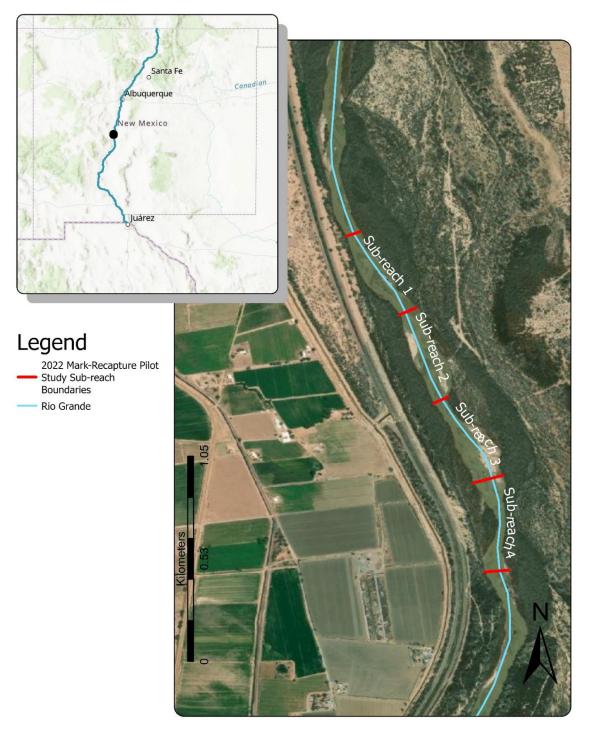

were abundant and we chose not to tag other species of fish. All RGSM captured were >30 mmin length and VIE tagged.

525 Fish were marked with a unique VIE color in one of several locations, allowing movement among sub-reaches to be inferred. We used orange VIE for sampling trip 1 and 526 yellow VIE for sampling trip 2. The location of the VIE mark indicated which sub-reach the fish 527 was caught in, starting with the pre-dorsal for sub-reach 1 and moving clockwise around the 528 dorsal fin for the other three reaches (Figure 2). Days 1 and 2 were repeated on days 3 and 4 to 529 increase the numbers of marked fish (i.e., no fish were double-tagged with the same color and 530 position during the second pass). During the third sampling trip, we did not mark any new fish 531 and only noted if the fish did or did not have a VIE tag from a previous trip. 532 Additionally, we examined mortality due to handing and marking. We collected 90 533 RGSM and tagged 50 with VIE. All fish were held in the same mesh cage, approximately 1-m 534 by 1-m and placed in a pool approximately 0.6 m deep. We held fish for 3 days and counted 535

537

536

mortalities.

544

## 545 Results, Discussion, and Recommendations

Compared to 2022, many fish were captured in total. We did not attempt to count other
species after the first pass. Among 4 total marking passes (640 seine hauls), we collected 2,861
RGSM. No fish were marked in the fifth and final pass, and we collected one additional 738 Rio
Grande Silvery Minnow. All Rio Grande Silvery Minnow were large enough to be marked.
Summary of capture histories are given Table 1.

The number of target species may allow use of mark-recapture models. Despite capturing three orders of magnitude more fish in 2023, the length of stream and number of seine hauls is reasonable to sample in a 4-day sampling period. Unfortunately, recaptures were still relatively low. Potentially, shortening the time interval between marking events may increase the number of recaptures, as our results make it evident that capture probability\*availability is low, fish are moving among segments and likely out of the study area, and we are increasing mortality by handling fish. We observed 5% mortality in unmarked fish during the cage study, whereas marked fish had 16% mortality. Moving sampling dates to later in September may also

improve handling survival as fish appeared to be in markedly better physical condition in

560 October samples.

561

562 Table 1-Frequency of mark-recapture histories for batch-marked Rio Grande Silvery Minnow in

563 September and October of 2023. Fish were captured in four contiguous 400-m sections of the

564 Middle Rio Grande during two marking periods (T1 and T2) with two passes each (P1 and P2),

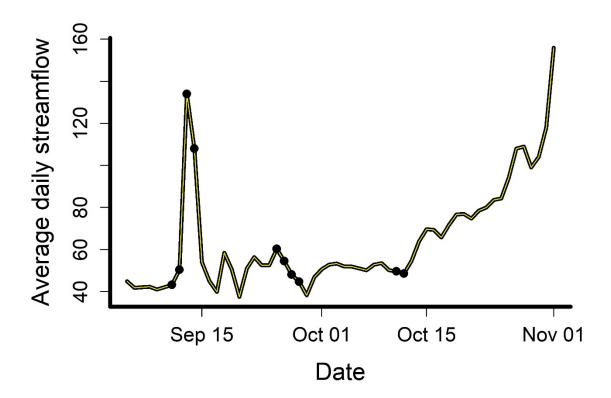

and one recapture period sampled with a single pass (T3). Cell number indicate in which of the

566	four sections	fish were	marked an	nd recaptured.

Streamflow was relatively stable among sampling periods (Figure 3). However, a small 568 flow pulse occurred between time period 1 and 2. Number of fish captured remained similar, but 569 570 fish may have redistributed during flow increases (Franssen), reducing the number of recaptures. Accounting for movement during lower, stable flows will be critical to determining fish turnover 571 due to movement during floods. Our primary recommendation for 2024 is to condense sampling 572 to consecutive weeks and begin in autumn to improve survival and recapture. Regardless of the 573 574 sampling methods, if there are not sufficient numbers of Rio Grande Silvery Minnow in the sampling segment to allow recapture within and among time periods, no estimates of survival, 575 movement, or abundance can be made. 576
