## DISCLAIMER

The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

## EXECUTIVE SUMMARY

- This report covers New Mexico Fish and Wildlife Conservation Office (NMFWCO) Rio Grande Silvery Minnow (RGSM) augmentation activities for the 2024 cohort.
- Spring runoff in early 2024 was moderate, resulting in a request of 210,000 hatchery-reared age-0 fish to supplement the wild 2024 cohort.
- Broodstock collections April through July 2024 resulted in 220 RGSM eggs (transported to the Albuquerque BioPark), ~2,500 larval RGSM (transported to the Albuquerque BioPark), and ~750 juvenile RGSM (transported to Southwestern Native Aquatic Resources and Recovery Center). This resulted in approximately 1,800 surviving broodstock, with only 300 housed at Southwestern Native Aquatic Resources and Recovery Center.
- Based on September 2024 population monitoring, the San Acacia and Angostura Reaches had  $> 1.0$  RGSM per  $100\text{m}^2$  but  $<50\%$  occupied sites and CPUE = 0.07 in the Isleta Reach. Because the Angostura Reach was only slightly above 1.0, the NMFWCO requested additional fish be released there, leading to a final request of 130,000 RGSM for release in the San Acacia Reach.
- 163,206 hatchery-reared age-0 Rio Grande Silvery Minnows were released in October, November, and December 2024. All were given a red left VIE tag prior to release.
- 109 VIE-marked fish were recaptured between January and December 2024, all from the 2023 cohort. The majority of recaptures ( $N = 105$ ) were during fish rescue activities.
- A pilot mark-recapture study continued in 2024 to determine the feasibility of robust-design mark recapture to estimate monthly survival, movement, and capture efficiency of Rio Grande Silvery Minnow. A total of 962 Rio Grande Silvery Minnow was captured in 2024 with 26 recaptures.

In 2001, the Rio Grande Silvery Minnow *Hybognathus amarus* (RGSM) Augmentation Plan (USFWS 2001) was developed to help prevent extinction of the species by increasing their numbers in the Rio Grande. Since that time, >3 million hatchery reared RGSM have been released into the Middle Rio Grande (MRG), New Mexico. The initial goal of the RGSM Augmentation Plan was to produce 500,000 RGSM each year for release based on the expected capacities of propagation facilities, along with current population status and suggestions from geneticists. Stocking and monitoring efforts were focused on the Angostura Reach (also known as the Albuquerque Reach) where catch rates of wild RGSM were extremely low and the expected benefit of augmentation could be maximized (Remshardt and Davenport 2003). However, actual production and tagging has been limited to 300,000 or less per year since 2010 and stocking has occurred in the Angostura, Isleta, and San Acacia Reaches when needed based on autumn abundance.

Varying numbers of RGSM have been released in the MRG each year ranging from 0 to 400,000 depending on river conditions. Between 2002 and 2004, 100,000 to 200,000 RGSM were released annually in the Angostura Reach. Annual releases were based on calculations to reach target densities of 1 fish/100m<sup>2</sup>. Starting in 2005, augmentation expanded to include the Isleta and San Acacia Reaches. In addition to augmentation and other conservation measures such as habitat improvement, improved spring runoff and habitat conditions improved survival in 2005 allowing RGSM to increase in abundance. Between 2005 and 2007, 100,000 to 400,000 RGSM were released annually throughout all reaches (Remshardt 2008). In 2008, USFWS began implementing a revised 5-year RGSM Augmentation Plan, in which the Angostura Reach was purposely not stocked in order to evaluate the effect of hatchery augmentation. Favorable spring run-off conditions for recruitment beginning in 2008 meant that no augmentation was needed that year; however, the number of RGSM stocked during the low spring run-off years of 2012 to 2014 was near maximum capacity of production facilities. Following slightly increased recruitment in 2015 and 2016, the 2017 cohort of RGSM was one of the strongest observed in the MRG. Declines during the drought years of 2020-2021 lead to an increase in the numbers of hatchery fish released.

170           This report summarizes augmentation planning and release activities during the 2024  
171 calendar year. This effort addresses management needs identified in Item A.2.2 of the Middle  
172 Rio Grande Endangered Species Collaborative Program (MRGESCP), Tasks 8b and 8d of the  
173 Rio Grande Silvery Minnow Recovery Plan, 1<sup>st</sup> Revision, (Recovery Plan; USFWS 2010), and  
174 Reasonable and Prudent Measure #5 of the Biological Opinion (USFWS 2016). These tasks  
175 include development and refinement of augmentation protocols for use in the Middle Rio Grande  
176 (Task 8b) and annual monitoring of augmented populations is identified as a needed task (Task  
177 8d).

178           A recovery outcome of a self-sustaining population of RGSM in the Middle Rio Grande  
179 requires numerous actions outlined in the Recovery Plan. The goal of augmentation is to support  
180 the wild population of RGSM in the Middle Rio Grande by bolstering resistance and resilience to  
181 disturbance and other environmental stressors (Archdeacon et al. 2023), until such time the  
182 population is self-sustaining. Augmentation accomplishes this goal by improving the abundance  
183 and distribution of RGSM in the Middle Rio Grande, thereby improving the demographic  
184 resilience of the species. Long-term objectives of this project are to promote the recovery of  
185 RGSM through 1) augmenting populations within the MRG with hatchery-raised fish as  
186 necessary; and 2) evaluating stocking efforts and methods to improve effectiveness of these  
187 actions.

188           Specific objectives of augmentation in 2024 were to implement the 5-year augmentation  
189 and stocking protocol (Archdeacon 2022), including assisting with spring production estimates,  
190 collection of eggs for broodstock and refuge populations, and calculating the number of RGSM  
191 necessary to meet target densities of 1 fish/100m<sup>2</sup> within each reach.

## METHODS

200 *Study Area*

201 This investigation concentrated on areas within the Angostura, Isleta, and San Acacia  
202 reaches (Figure 1). The Angostura Reach (~65 km) extends from Angostura Diversion Dam to  
203 Isleta Diversion Dam and includes the cities of Bernalillo, Corrales, and Albuquerque. The  
204 Isleta Reach (~54 km) extends from Isleta Diversion Dam to San Acacia Diversion Dam, and  
205 includes the southern portion of Isleta Pueblo, cities of Bosque Farms, Valencia, Los Lunas,  
206 Belen, and smaller villages such as La Joya, and Bernardo, along with Sevilleta National  
207 Wildlife Refuge, all within Bernalillo, Valencia, and Socorro Counties. The San Acacia Reach  
208 (~76 km) extends from San Acacia Diversion Dam to the headwaters of Elephant Butte  
209 Reservoir (the exact location of the lower boundary varies depending upon reservoir water-  
210 surface elevation). This reach is relatively remote, including only the city of Socorro and  
211 villages of San Acacia, Lemitar, Escondida, and San Antonio along with Bosque del Apache  
212 National Wildlife Refuge, within Socorro and Sierra Counties.

213

214 *Spring Estimation of Production Needs*

215 Hatchery facilities must plan for spring spawning by May of each year and require  
216 estimates of numbers of fish needed for autumn augmentation. Spring planning numbers are  
217 estimated from the April 1 streamflow forecast of each year and are incorporated in a generalized  
218 linear regression model that is updated with new data each year (Figure 2). The forecasted 50%  
219 exceedance streamflow, in thousands of acre-feet (KAF), March through July at the Otowi gage  
220 (available at  
221 <https://www.nrcs.usda.gov/wps/portal/wcc/home/snowClimateMonitoring/snowpack/basinDataR>  
222 [eports/](#)) is used to predict the actual numbers of fish released in the autumn (described below).  
223 As more years are included, the model will be able to incorporate other parameters, including  
224 existing numbers of fish from previous cohorts, which should improve both the precision and  
225 accuracy of predictions. A generalized linear regression model was used to relate actual  
226 numbers of fish needed to the spring forecast. As a conservative measure, the upper 95%  
227 confidence interval is used for the spring estimation of augmentation needs.

228

229 *Collection of Wild-caught Eggs for Broodstock and Refuge Population*

230 Rio Grande Silvery Minnow spawning typically occurs in May and June (Archdeacon et  
 231 al. 2023a). Rio Grande Silvery Minnow release semi-buoyant, non-adhesive eggs directly into  
 232 the water column (Platania and Altenbach 1998). During times of high spawning activity and  
 233 lower discharge, eggs can be easily collected from the river (Altenbach et al. 2000). These eggs  
 234 may be transported to rearing facilities to serve as broodstock or a refuge population or returned  
 235 to the river in years when large numbers are collected (Archdeacon et al. 2023). During high-  
 236 flow years, larvae or juveniles are collected during summer and autumn months.

237

238 *Autumn Estimation of Augmentation Needs*

239 Following the revised RGSM Augmentation Plan 2018-2022 (Archdeacon 2022),  
 240 augmentation efforts were focused on all three reaches (Angostura, Isleta, and San Acacia) in  
 241 2024. September catch-rates (e.g., catch-per-unit-effort; fish/100m<sup>2</sup>) from preliminary  
 242 population monitoring results (R. Dudley, personal communication) were used as criteria to  
 243 determine the need for augmentation and the number of fish required. If the entire reach average  
 244 was >1.0 fish/100m<sup>2</sup> and >50% of monitoring sites were occupied, then augmentation was not  
 245 required. If either of the criteria were not met, augmentation occurred and the total number of  
 246 fish for the reach was calculated as given below (Archdeacon 2022). Surface area between sites  
 247 was estimated from aerial imagery and average wetted conditions.

248

249 The number of fish to augment for each site ( $S_i$ ) was determined using the following  
 250 formula:

$$251 \quad S_i = (C_t - C_o) \times (\text{total estimated area } m^2 \text{ between } S_i \text{ and } S_{i+1})$$

252 where;  $C_t$  = Target catch rate at each site, or 1 fish / 100 m<sup>2</sup>,

253  $C_o$  = Observed catch rate at site  $i$  in September

254  $S_i$  = Number of fish to release at site  $i$

255  $S_{i+1}$  = Next downstream site of site  $i$

256 Once the required number of fish per site was determined, it was summed per  
 257 reach. The total number of fish per reach was spread among at least three release  
 258 locations per reach.

259

260 *Fish Condition Factor*

261 We weighed (0.01 g) and measured (1 mm) standard and total length of at  
262 least 100 haphazardly selected (and assumed representative) fish from each  
263 facility. We calculated Fulton's condition factor ( $K_{tl}$ ; see Froese 2006) for these  
264 fish; augmentation guidelines are that fish should be 45 mm TL and have a  
265 condition factor of  $K_{tl} > 0.80$  to improve survival and reproduction post-release  
266 (Archdeacon 2022).

267 *Tagging*

268 Tagging followed the standard operating procedures for tagging Rio Grande Silvery  
269 Minnow with VIE tags. For fish released in 2024, tags were placed in the left dorsal position.  
270 All facilities used red VIE tags for marking.

271

272 *Fish Releases*

273 Rio Grande Silvery Minnow are loaded in large transport tanks at the hatcheries and are  
274 transported to a site where trucks can get close to flowing water. River water was used to temper  
275 the tanks to within 1°C of the river water. The RGSM are then released directly from the trucks  
276 into areas of low or zero velocity water at stocking sites. If the transport trucks are unable to get  
277 access to the river, RGSM are loaded into smaller transport tanks in the back of off-road vehicles  
278 following transport protocols developed for RGSM fish rescue along with the tempered water,  
279 and then driven to the river and released into low velocity habitats. Specific timing and release  
280 sites are chosen to avoid releasing fish directly at standard monitoring sites. A minimum of three  
281 release locations are chosen for each reach, based on the areas with the lowest densities and river  
282 access (Archdeacon 2022).

283

284 *Recapture Data from Other Researchers*

285           Recapture data collected from other researchers continue to provide valuable information  
286 on movement and survival of VIE marked fish. Included in this year's summary are collections  
287 from standard population monitoring work for RGSM conducted by ASIR (American Southwest  
288 Ichthyological Researchers, LLC), data from NMFWCO RGSM fish rescue projects, the U.S.  
289 Bureau of Reclamation, and the University of New Mexico (UNM) genetic monitoring. These  
290 researchers were asked to provide recapture information on VIE-marked RGSM. These projects  
291 have varying objectives and methods, but a summary of recaptures can provide an overall view  
292 of RGSM movement and retention in release areas.

293

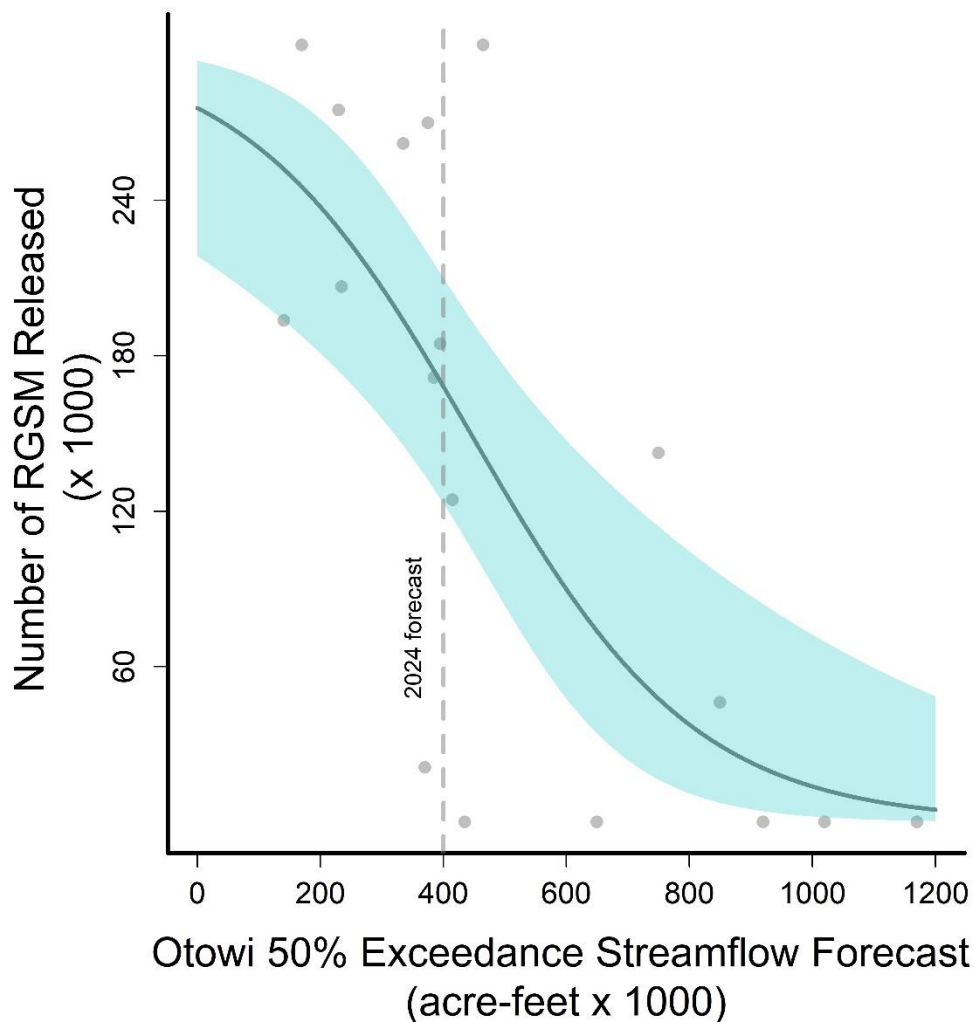

294

## 295 RESULTS

296 *Spring Estimation of Production Needs*

297 The forecasted 50% exceedance flow at Otowi for March through July was 400 KAF  
298 (Figure 2). This resulted in a request for 210,000 age-0 Rio Grande Silvery Minnow to be  
299 spawned and reared for augmentation in autumn.

300

301

302 Figure 2- Association between numbers of Rio Grande Silvery Minnow released in autumn and  
303 the forecasted spring-summer streamflow at the Otowi gage in the Rio Grande, New Mexico.

304 The gray area represents the 95% confidence interval for numbers of hatchery fish actually  
305 required in each year. The model is updated yearly. The dashed line represents the forecasted  
306 2024 spring flows and is used to estimate hatchery production of age-0 RGSM in May.

307 *Collection of Wild-caught Eggs for Broodstock and Refuge Population*

308 An early peak of flows in April stimulated spawning. Few eggs were collected as staff  
309 were not prepared for collections that early. In total, NMFWCO staff collected 220 eggs on 8  
310 separate days were observed, and 64 transported to the Albuquerque BioPark for rearing. Use of  
311 larval light traps resulted in ~1,000 RGSM transferred to the Albuquerque BioPark for rearing.  
312 Staff were able to collect 772 young-of-year with seines in June and July (Appendix A). These  
313 fish were treated for infections and reared to a size large enough to identify. After identification,  
314 these fish were transferred to the Albuquerque BioPark or SNARRC.

315

316 *Estimation of Augmentation Needs*

317 Based on September 2024 catch rates from the standard RGSM monitoring program  
318 conducted by ASIR, the Angostura and San Acacia Reaches had CPUE > 1.0 fish 100 m<sup>-2</sup>, but  
319 the Isleta Reach had < 50% site occupancy and CPUE = 0.07 (Table 1). The Isleta Reach  
320 required 79,000 RGSM for augmentation. However, the Angostura Reach CPUE was only 1.06  
321 and an additional 50,000 were released there were excess fish from the spring request.

322 Table 1- Rio Grande Silvery Minnow monitoring sites, approximate surface area (ha) between it  
 323 and the next site downstream during baseflows, and observed CPUE in September 2024, in the  
 324 Middle Rio Grande, New Mexico. DD = Diversion Dam, NWR = National Wildlife Refuge,  
 325 RRWWTP = Rio Rancho Wastewater Treatment Plant, SM = San Marcial. \*No stocking was  
 326 necessary because CPUE was  $> 1.0$  fish  $100\text{ m}^{-2}$  and reach occupancy  $> 0.50$ .

328 *Fish Condition Factor*

329 Fish were weighed and measured 23 October (LLSMR and BioPark), or 20 November  
330 2024 (Southwestern ARRC). Fish from Southwestern ARRC averaged 48.6 mm TL and had an  
331 average  $K_{tl} = 0.93$ . Fish from the LLSMR averaged 60.8 mm TL and had an average  $K_{tl} = 0.81$ .  
332 However, fish from the LLSMR 2023 (age-1) captive spawned fish averaged 66.8 mm TL and  
333  $K_{tl} = 0.80$ , whereas the 2024 (age-0) captive spawned fish and in the outdoor refugium averaged  
334 54.8 mm TL and  $K_{tl} = 0.82$ . Fish from the Albuquerque BioPark averaged 51.1 mm TL and had  
335 an average  $K_{tl} = 0.90$ .

336

337 *Tagging*

338 Tagging was completed at Southwestern ARRC, Albuquerque BioPark, and Los Lunas  
339 SMR. All fish were given red left VIE markings.

340

341 *Fish Releases*

342 A total of 163,206 RGSM were released at five sites in 2024 (Figure 1, Table 2). Two  
343 sites were located in the Angostura Reach (N = 50,145) and the remaining three sites in the Isleta  
344 Reach (N = 113,061). Additional fish were available and released in the Isleta Reach, above and  
345 beyond the requested amount.

346

347 *Recapture Data*

348 A total of 109 VIE-marked fish were recaptured between January and December 2024.  
349 Of these, 105 were from the 2023 release cohort. The majority of recaptures (N = 1055) were  
350 during fish rescue activities.

351

352

Over the preceding decade, RGSM densities have varied greatly from year to year. Beginning in 2015, numbers began to increase through 2017. In 2017, high spring runoff led to very high densities of RGSM. However, after poor recruitment in 2018 and 2020-2022, the annual numbers of fish needed for augmentation increased. The association between the spring hydrograph and the density of RGSM detected the following October is well established (Yackulic et al. 2022). The spring 2023 estimate based on forecasted streamflow suggested no fish would be needed in the autumn, but 60,000 were requested as minimum production. The high spring runoff peak prevented large egg collections, but many larvae and juveniles were collected when flows began to recede. However, considerable drying in the San Acacia Reach resulted in the need to stock fish, as <50% of the monitoring sites had RGSM present. There is still considerable variability and uncertainty in autumn planning needs when average flows are between approximately 50 and 80%, though the years 2010 and 2018 appear to be outliers. As more data is collected, this relationship should be clarified, allowing for more precise estimates of augmentation needs in spring. The variability may be linked to the abundance of the previous years' cohort.

Fish from all Southwestern ARRC, LLSMR, and the BioPark were generally in good condition ( $K_{II} < 0.80$ ). Approximately 30,000 age-0 fish were held back at the Southwestern ARRC to help evaluate how body condition and size of hatchery fish influences survival and performance after release. Making these determinations will help guide and improve propagation practices.

Rio Grande Silvery Minnow exhibit an opportunistic life-history with high demographic resilience (Winemiller 2005), with short generation times, high reproductive effort (Caldwell et al. 2019), high mobility (Archdeacon et al. 2018, Platania et al. 2020), and a short lifespan (Horwitz et al. 2018). Having high demographic resilience allows the population to rebound quickly after disturbance. Over the previous five years, populations increased in 2017, followed by four years of extreme annual variability in spring runoff. Populations rebounded in 2019 after poor runoff and recruitment conditions in 2018 (Archdeacon et al. 2020). Thus, continued augmentation will be necessary in some years if spring run-off continues to be low and below average and no other options to improve recruitment exist. However, continued and heavy hatchery augmentation to stave off extinction has eroded RGSM genetics (Osborne et al. 2024).

389 Further refinement of production, release, as well as refining release numbers may help improve  
390 the effectiveness of augmentation but will not replace habitat and flow restoration.

392

#### ACKNOWLEDGEMENTS

393 Thanks to the many individuals who contributed to this project in 2024 including Lyle  
394 Thomas, and Paige Dunnum from NMFWCO, Ty Terry, Jesse Trujillo, and William Knight  
395 from the Southwestern Native Aquatic Research and Recovery Center. The University of New  
396 Mexico, U.S. Bureau of Reclamation, and American Southwest Ichthyological Researchers LLC  
397 provided technical advice and/or support during various phases of the project. This work was  
398 funded through and interagency agreement with the U.S. Bureau of Reclamation Area Office in  
399 Albuquerque, New Mexico.

476 **Introduction**

477           The Rio Grande Silvery Minnow is a small-bodied minnow that currently only found in  
478 the Rio Grande in central New Mexico. The range of the Rio Grande Silvery Minnow  
479 (*Hybognathus amarus*) has been severely reduced and it now inhabits only 5% of its historical  
480 range, occurring from Cochiti Dam downstream to Elephant Butte Reservoir (Bestgen and  
481 Platania 1991). This loss of habitat has been caused by fragmentation due to dams constructed  
482 for water diversions, which has also led to modified flow regimes and periodic channel drying  
483 during summer months. Due to this decline, the Rio Grande Silvery Minnow was listed as  
484 endangered in 1994 (USFWS 1994) and since then has been the focus of regular monitoring,  
485 augmentation, and relocation during dewatering (USFWS 2010). In order to evaluate recovery  
486 efforts, catch per unit effort (CPUE) is used as a metric as part of both the Rio Grande Silvery  
487 Minnow Recovery Plan and Annual Augmentation Plan.

488           In support of improving the knowledge of the biology and ecology of Rio Grande Silvery  
489 Minnow, the New Mexico FWCO will work to improve the reliability of the CPUE metric.  
490 Several reviews of the long-term population monitoring program (e.g., Dudley et al. 2022) have  
491 recommended determining additional studies on the relationship between CPUE and abundance  
492 and developing correction factors to account for variable capture efficiencies among sites, years,  
493 and discharges (Hubert et al. 2016; Noon et al. 2017) improve the reliability of CPUE.

494           Capture-recapture is the gold standard in wildlife and fisheries studies for making  
495 inferences about demographic rates and overall abundance. While it is possible to estimate these  
496 quantities without marking individuals, approaches that rely on unmarked fish are less precise  
497 and less robust to violations of assumptions. For managers, the costs of imprecise estimates are a  
498 poorer understanding of the drivers of population dynamics and less clarity regarding the  
499 appropriate management responses. In recent years, modelling approaches have been developed  
500 to integrate intensive capture-recapture data collected over limited spatial scales and temporal  
501 scales with more extensive, but less informative data (e.g., catch per unit effort data) to reach  
502 robust inferences that build on the relative strengths on these two data types. Survival and  
503 abundance estimate from RGSM capture-recapture would be invaluable for evaluating estimates  
504 from models based on cruder data and would be integrated to improve our overall understanding

505 of RGSM demography and the impacts of various management actions on RGSM population  
506 dynamics.

### 507 *Objectives*

508         The overarching objectives of this mark-recapture study is to estimate abundance of Rio  
509 Grande Silvery Minnow within a small section of the MRG, estimating and accounting for  
510 survival between sampling periods, immigration and emigration between sampling periods, and  
511 capture efficiency. After sampling in multiple areas and years, we plan to synthesize results to  
512 improve the utility of CPUE, which can be collected on a much larger spatial scale with less  
513 effort. We determined that an initial pilot study would be beneficial to determine the feasibility  
514 of initial study design and expected recapture rates. Full methodology will be developed after  
515 this initial study and yearly review. Here, we examined sub-reach lengths and number of hauls  
516 that would be reasonable to sample to determine expected capture and recapture rates. These  
517 may need to be adjusted during years of high abundance. Visible implant elastomer (VIE) tags  
518 will be used to mark RGSM and surrogate species greater than 30 mm standard length (SL), the  
519 color and placement of the tag indicating the time period and sub-reach in which it was caught.  
520 Thus, both capture history and movement among sub-reaches can be determined and used to  
521 estimate population size, capture efficiency of seines, monthly survival, and to a limited extent,  
522 movement. Here we summarize the 2024 efforts and compare changes in methodology as well  
523 as RGSM catch rates.

524

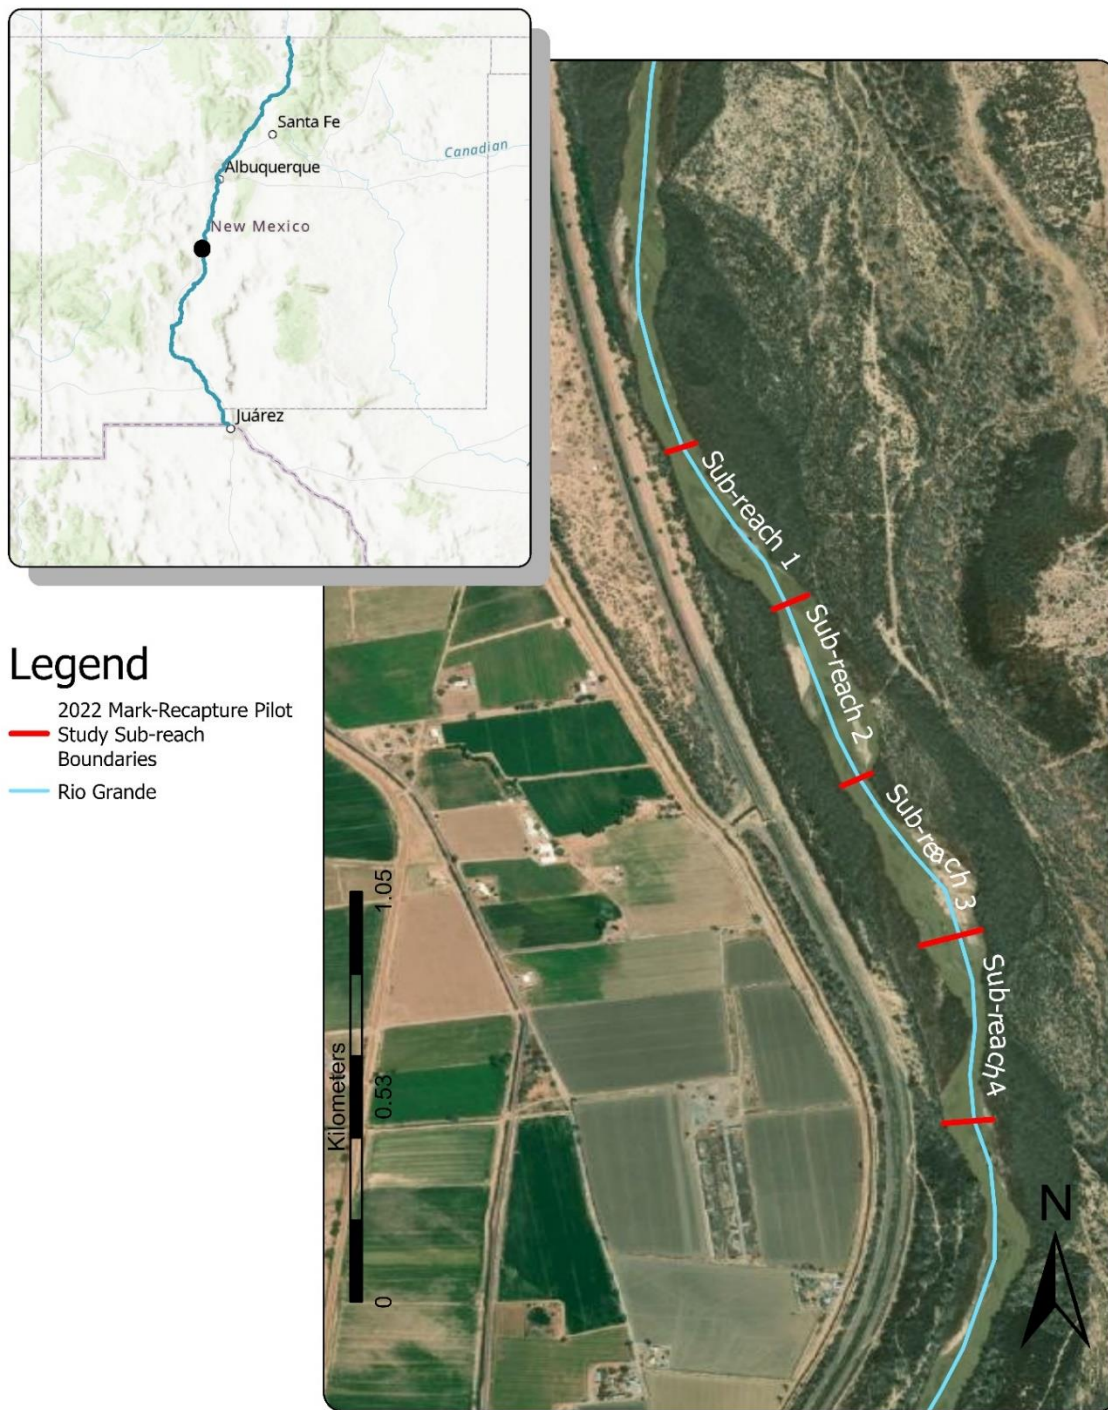

### 525 **Methods**

526         For the third year of the initial pilot study, a 1.6 km portion of the San Acacia reach was  
527 chosen and divided into four equal-length sections of 400 m (Figure 3). The sampling location  
528 was chosen arbitrarily with the intention of having relatively more RGSM present for capture  
529 because it has not experienced river drying in at least the past two decades (Archdeacon and  
530 Reale, 2020) and had a variety of mesohabitats present. This was the same area used in 2022 and  
531 2023. We conducted sampling four times, one week apart, covering a total sampling period of  
532 four weeks. Sampling began on September 23 and concluded October 16. On the first day, sub-  
533 reaches 1 and 2 were sampled by conducting 10 seine hauls per 100 m of stream length, totaling  
534 40 seine hauls per sub-reach. We employed a seine (3.0 x 1.0 m, mesh size = 3.2 mm) and varied  
535 the habitat and length evaluated as much as possible. On the second day, sub-reaches 3 and 4

536 were sampled with the same methodology. All RGSM captured were >30 mm in length and VIE  
537 tagged.

538 Fish were marked with a unique VIE color in one of several locations, allowing  
539 movement among sub-reaches to be inferred. We used yellow VIE for sampling trip 1, green  
540 VIE for sampling trip 2, and orange VIE for sampling trip 3. The location of the VIE mark  
541 indicated which sub-reach the fish was caught in, starting with the right pre-dorsal for sub-reach  
542 1 and moving clockwise around the dorsal fin for the other three reaches (Figure 4). Methods on  
543 days 1 and 2 were repeated on days 3 and 4 to increase the numbers of marked fish (i.e., no fish  
544 were double-tagged with the same color and position during the second pass). During the fourth  
545 sampling trip, we did not mark any new fish and only noted if the fish did or did not have a VIE  
546 tag from a previous trip.

547

548  
549 Figure 3- Map depicting the location of the 2022-2024 mark-recapture study and the division of  
550 the sub-reaches along the 1.6 km long reach.

 553 sub-reach where the fish was captured.

554

### 555 **Results, Discussion, and Recommendations**

556 We caught fewer RGSM in 2024 compared to 2023, but still captured a considerable  
 557 number of RGSM. Among 6 total marking passes (960 seine hauls), we collected 792 unmarked  
 558 RGSM. No fish were marked in the seventh and final pass, and we collected an additional 144  
 559 Rio Grande Silvery Minnow. We recaptured 26 RGSM in total. All RGSM were large enough to  
 560 be marked. Summary of capture histories are given Table 1.

561 The number of target species may allow use of mark-recapture models. Despite  
 562 capturing three orders of magnitude more fish in 2023, the length of stream and number of seine  
 563 hauls is reasonable to sample in a 4-day sampling period. Unfortunately, recaptures were still  
 564 relatively low. Potentially, shortening the time interval between marking events may increase  
 565 the number of recaptures, as our results make it evident that capture probability\*availability is  
 566 low, fish are moving among segments and likely out of the study area, and we are increasing  
 567 mortality by handling fish.

568 Table 1-Frequency of mark-recapture histories for batch-marked Rio Grande Silvery Minnow in  
 569 September and October of 2023. Fish were captured in four contiguous 400-m sections of the  
 570 Middle Rio Grande during three marking periods (T1, T2, and T3) with two passes each (P1 and  
 571 P2), and one recapture period sampled with a single pass (T4). Cell number indicate in which of  
 572 the four sections fish were marked and recaptured.

573

574 Streamflow was relatively stable among sampling periods (Figure 3). However, a small  
575 flow pulse occurred between time period 1 and 2. Number of fish captured remained similar, but  
576 fish may have redistributed during flow increases (Franssen), reducing the number of recaptures.  
577 Accounting for movement during lower, stable flows will be critical to determining fish turnover  
578 due to movement during floods. Our primary recommendation for 2024 is to condense sampling  
579 to consecutive weeks and begin in autumn to improve survival and recapture. Regardless of the  
580 sampling methods, if there are not sufficient numbers of Rio Grande Silvery Minnow in the  
581 sampling segment to allow recapture within and among time periods, no estimates of survival,  
582 movement, or abundance can be made.

583

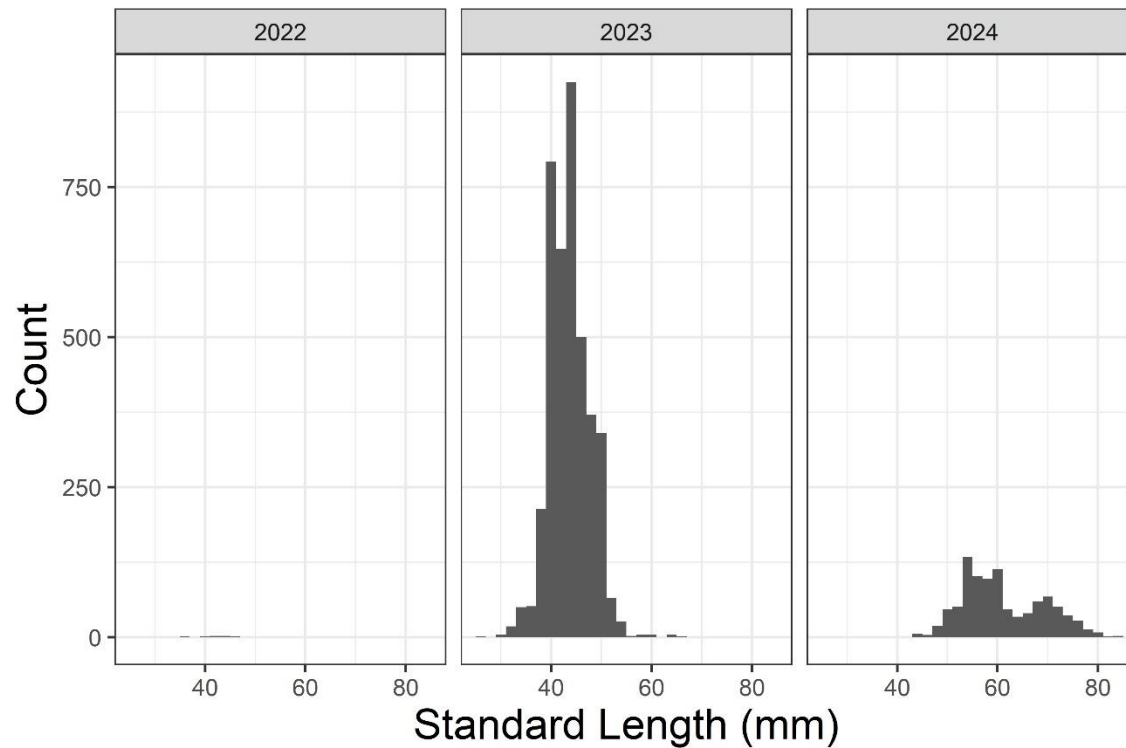

584

585 Figure 3-Streamflow (cfs) at the Escondida gage (U.S.G.S. gage 08355050) during the mark-  
586 recapture study period in the Middle Rio Grande, 2023. Points indicate days sampling occurred.

587

588 Fish lengths over the entire three years were variable by year reflecting patterns of both  
589 recruitment and growth (Figure 4). In 2022, very few fish were captured. In 2023, nearly all fish  
590 captured were age-0, with a modal standard length around 45 mm. However, in 2024, there  
591 appears to be a bi-modal distribution of lengths, with peaks around 57 mm and 70 mm,  
592 suggesting two age classes of Rio Grande Silvery Minnow present. However, age-2 fish would  
593 have been hatched in 2022, during a year of low recruitment. Other explanations for the bi-  
594 modal peak overserved in 2024 could be different growth rates among fish within a cohort  
595 leading to the bi-modal pattern, or simply sampling error. Without the context of the time-series,  
596 the two peaks could easily be mistaken for two different year-classes, but this is unlikely as only  
597 seven fish were captured in 2022, and a clear peak of age-1 fish does not appear in 2023.

598

599 Figure 4-Standard lengths of Rio Grande Silvery Minnow captured by year during a mark-  
600 recapture study in the San Acacia Reach during September and October each year.

601 In 2024, we sampled weekly as opposed to bi-weekly as in 2022 and 2023. Decreasing  
602 the time period between sampling events may have increased the number of recaptured fish. The  
603 low number of recaptures is likely attributable to movement outside the study area, low weekly  
604 survival, and low capture efficiency.

#### 605 **Acknowledgments**

606 We thank Charles Yackulic for discussion on the initial planning and refinements. We  
607 thank staff from the the U.S. Bureau of Reclamation for assistance with field collections.
