PROJECT SUMMARY

It is widely known that the health of fish can be adversely affected by exposure to water pollution. In 2005, the Middle Rio Grande Endangered Species Act Collaborative Program (Collaborative Program) requested proposals for monitoring the health conditions of Rio Grande silvery minnow (*Hybognathus amarus*; RGSM) in the mainstem of the Middle Rio Grande. In response, the U.S. Fish and Wildlife Service (Service) designed the RGSM Health Study to monitor and characterize the health conditions of RGSM in the MRG to provide baseline data on diseases and parasites, and document external and internal anomalies and pathologies in fish collected throughout the year. The Collaborative Program also requested that monitoring of RGSM health conditions be conducted in conjunction with a water-quality monitoring program to better link results to possible causes. In particular, the New Mexico Environment Department (2009) implemented (and reported separately) a companion water quality study that overlapped some of the same sites sampled during this RGSM Health Study.

Various agencies participated in the RGSM Health Study including the New Mexico Environment Department (NMED); the University of New Mexico, Museum of Southwestern Biology (Museum); the U.S. Geological Survey (USGS), New Mexico Ecological Services Field Office, and Dexter Fish Health Unit. We conducted the RGSM Health Study from July 2006 to July 2008 (Year 1 and Year 2). Rio Grande silvery minnows (*Hybognathus amarus*) were collected nearly every three months from six sites in the Rio Grande from Bernalillo to San Antonio, New Mexico. We used a suite of standard methods of observation of fish health conditions during necropsy to determine total length, mass, organ condition, the number and type of lesions and anomalies, the number and type of parasites and pathogens, and we analyzed their tissues for a variety of chemicals and genetic conditions. We also measured surface water quality parameters (i.e., dissolved oxygen (DO), oxygen saturation, temperature, pH, specific conductivity).

There are three chapters of this RGSM Health Study Report with three additional reports included as appendices, which describe the different activities undertaken during this RGSM Health Study. Chapter 1 includes introductory materials, selection of study sites, methods of fish and water quality data collection, results, and discussion including the use of oxygen measures to evaluate gross primary productivity (GPP) and ecosystem respiration (ER). Chapter 2 includes the Fish Health Assessment methods, necropsy results, and discussion. Chapter 3 includes the analytical methods, results, and discussion of chemicals in RGSM tissues. Literature cited and data appendices (Appendices 1A-1C, 2A-2K, and 3A-3F) are provided with the first three chapters. Some materials were made available online at http://www.fws.gov/southwest/es/newmexico/EC_reports.cfm. Appendix 4 includes the Fish Histology and Histopathology Report by Papoulias et al. (2009). Appendix 5 includes the Fish Pathogen Assessment Report that included methods of RGSM pathogen data collection, results, and discussion by Woodland (2012). Appendix 6

includes the Genetic Evaluation Report by Osborne and Turner (2009). Each chapter or appendix report also refers to their own figures, tables, and data appendices. We measured individual fish and dissected them to observe their external and internal conditions (Chapter 2). We measured total length and weight and found fish collected in Year 1 were significantly larger than those collected in Year 2 were. We found a significant relationship between fish length and weight with average annual water temperature. We observed shortened opercula, gill pathologies, liver anomalies, and degenerated kidney tubules as anomalies with the greatest frequency and these anomalies were observed at a greater frequency in Year 2 than in Year 1. Changes in water temperature, nutrition, or discharge appeared to be the most likely factors affecting skeletal development and therefore shortened opercula in silvery minnows. Mean Feeding Index was significantly lower in Year 1 than in Year 2, suggesting that food was more readily available during Year 1. The percent of fish with anomalies or pathological lesions tended to increase from upstream to downstream. Generally, the health of the Rio Grande silvery minnows was moderately affected, indicative of chronic stress, deteriorated from Year 1 to Year 2, from upstream to downstream, and during the summer (as measured during July) (Chapter 2, Appendix 4, and Appendix 5).

Additionally, we collected samples of spleen, gonad, and other tissues for histopathological examination and hematology (Appendix 4). All silvery minnows observed were experiencing chronic stress likely associated with poor water or sediment quality as evidenced by a suite of health indicators. Those silvery minnows collected in July tended to be the least healthy, having more macrophage aggregates, granulomas, lower liver glycogen and increased spleen size with fewer red blood cells. Gill abnormalities (e.g., discoloration, fraying, clubbing, fused lamellae, embolism, and parasites) were commonly observed in over 96 percent of the silvery minnow gills and could be related to bacterial or parasite infestations, or elevated copper.

Female gonads were observed in 58 percent of samples, but percentage of females was not significantly different by sample year, site, or month. However, there was a significant trend of more females in samples collected sites downstream than upstream. We observed some atretic oocytes in females (i.e., ectopic oocytes in liver and kidney tissues); however, no oocytes were positively detected in the testes of males evaluated.

The majorities of livers were low to moderate in glycogen content, and were lowest in silvery minnows collected in July. While gross liver abnormalities were high (e.g., discolored or mushy liver), liver pathologies (e.g., edema, high fat content, pigments and macrophages, granulomas, parasites, etc.) were low. Granulomas and macrophage aggregates were more prevalent in July 2008 samples and hemosiderin and melanin pigments were more common in livers collected in Year 2.

After necropsy, the silvery minnow carcasses were chemically analyzed for a variety of metals, hydrocarbons, organochlorine compounds, stable isotopes, and fire

retardant residues (Chapter 3). Generally, organic chemical concentrations in silvery minnows were low. However, semivolatile hydrocarbons, especially naphthalene and other PAHs, were moderately elevated in silvery minnows. Several organochlorine pesticides, PCBs, and BDEs (flame-retardants), were also elevated in silvery minnows collected from Site 3 and Site 4. The bioaccumulation of chlorinated and brominated organic chemicals at these sites may have been related to silvery minnow size, lipid content, or potential site or dietary differences. Concentrations of inorganic contaminants in Rio Grande silvery minnow were similar to those in other fish species collected from the Rio Grande and were generally low, with the exception of aluminum, copper, nickel, vanadium, and zinc. Additional research was recommended for those contaminants in fish that were elevated.

We measured water quality parameters (e.g., dissolved oxygen, temperature, pH, and conductance) as well as used rates of oxygen change to estimate gross primary productivity and ecosystem respiration (Chapter 1). Average gross primary productivity rates ranged widely, but were generally higher at upstream sites and during summer. Low oxygen conditions were identified and were most likely associated with oxygen demanding substances in sediment. Increasing gross primary productivity and thereby increasing oxygen content will reduce oxygen demand and ecosystem respiration. Improvements in these conditions would likely result in increased populations of fish, increased species richness of benthic invertebrates, and decreased chronic stress reported in Rio Grande silvery minnows.

In a companion study, the New Mexico Environment Department (NMED 2009) evaluated the chemical quality of water, sediment and fish in the Middle Rio Grande. NMED evaluated chemical data in the water column to evaluate exceedances of New Mexico Water Quality Control Commission-approved water quality standards. The NMED (2009) concluded that very few water quality standards impairments were found. The NMED (2009) also evaluated water, sediment and fish tissue data to identify additional water quality issues of concern (i.e., issues that were not considered to exceed New Mexico water quality standards) and identified aluminum, copper, chromium, ammonia, low oxygen, elevated pH in water, zinc and DDT in fish tissues, and several semivolatile compounds (PAHs) in sediment as elevated. The Rio Grande Silvery Minnow Health Study findings were consistent with the NMED (2009) study.

In summary, the health of the Rio Grande silvery minnow was moderately impaired. The silvery minnows had skeletal deformities (i.e., shortened opercula) that suggested a causal association with factors of water temperature, nutrition, and/or discharge. Silvery minnows were generally healthier collected from upstream than from downstream sites. When water quality conditions deteriorated, including higher temperatures, lower oxygen content, and with increased pathogen burdens as were measured during July, the health of silvery minnows also generally declined. Several contaminants were prevalent in fish including hydrocarbons such as PAHs, and certain metals, including aluminum and zinc.

INTRODUCTION

Rationale and Purpose of Rio Grande Silvery Minnow Health Study

Malnutrition, metabolic disorders, and environmental stressors such as rapid changes in temperature, oxygen levels, suspended solids, salinity, toxic chemicals, or other physical, chemical and biological qualities of a river can stress fish (Heath 1995). Monitoring fish health conditions in conjunction with traditional water quality measures provides biologically relevant information about potential stressors in the environment and their effects on fish (Schmitt and Dethloff 2000, Smith et al. 2002). Fish health conditions are surveyed because fish are regarded as representative indicators of overall water quality conditions and because of their position in the water column and intimate exposure in the environment (Anderson 1990; Adams et al.1993; Heath 1995; Schmitt et al. 2004).

In 2005, the Middle Rio Grande Endangered Species Act Collaborative Program requested proposals (U.S. Bureau of Reclamation [BOR] 2005) for monitoring the health conditions of Rio Grande silvery minnow (*Hybognathus amarus*; RGSM) in the mainstem of the Middle Rio Grande (MRG; Figure 1). In response, the U.S. Fish and Wildlife Service (Service) designed the RGSM Health Study to monitor and characterize the health conditions of RGSM in the MRG. Monitoring the health conditions of RGSM was meant to provide baseline data on diseases and parasites, and document external and internal anomalies and pathologies in fish collected throughout the year. The BOR (2005) also requested that monitoring of RGSM health conditions be conducted in conjunction with a water-quality monitoring program to better link results to possible causes. Various agencies participated in the RGSM Health Study including the New Mexico Environment Department (NMED); the University of New Mexico, Museum of Southwestern Biology (Museum); the U.S. Geological Survey (USGS), New Mexico Ecological Services Field Office, and Dexter Fish Health Unit. In particular, the NMED (2009) implemented (and reported separately) a companion water quality study that overlapped some of the same sites sampled by this RGSM Health Study.

For this RGSM Health Study, we used a suite of standard methods of observation of fish health conditions during necropsy to determine total length, mass, organ condition, the number and type of lesions and anomalies, the number and type of parasites and pathogens, and we analyzed their tissues for a variety of chemicals and genetic conditions. We collected RGSM and evaluated their health conditions, observed disease and pathology, histopathology and other conditions quarterly from July 2006 through July 2008 at six sites in the MRG from Bernalillo to near San Antonio, New Mexico (Figure 1). We also measured surface water quality parameters (e.g., dissolved oxygen (DO), oxygen saturation, temperature, pH, specific conductivity) in conjunction with the NMED (2009) collection and analysis of water and sediment from these or nearby sites.

Chapters and Appendices of this Report

There are three chapters of this RGSM Health Study Report with three additional reports included as appendices, which describe the different activities undertaken during this RGSM Health Study. Chapter 1 includes introductory materials, selection of study sites, methods of fish and water quality data collection, results, and discussion including the use of oxygen measures to evaluate gross primary productivity (GPP), ecosystem respiration (ER). Chapter 2 includes the Fish Health Assessment methods, necropsy results, and discussion. Chapter 3 includes the analytical methods, results, and discussion of chemicals in RGSM tissues. The Project Summary reports all findings of our study and provides recommendations. Literature cited and data appendices (Appendices 1A-1C, 2A-2K, and 3A-3F) are provided with the first three chapters. Some materials were made available online at http://www.fws.gov/southwest/es/newmexico/EC_reports.cfm. Appendix 4 includes the Fish Histology and Histopathology Report by Papoulias et al. (2009). Appendix 5 includes the Fish Pathogen Assessment Report that included methods of RGSM pathogen data collection, results, and discussion by Woodland (2012). Appendix 6 includes the Genetic Evaluation Report by Osborne and Turner (2009). Each chapter or appendix report also refers to their own figures, tables, and data appendices. Additionally, the water quality report by NMED (2009) describes their methods, results, and implications of Rio Grande water quality to RGSM, as well as some of the analytic results from water, sediment, and fish samples at sites concurrently sampled with the RGSM Health Study, except for summer 2006 or summer 2007.

Permissions, Land Access, Consultations, and Agreements

The Service was granted vehicular access to the Middle Rio Grande and adjacent floodplain by issuance of Special Use License and gate key from the Middle Rio Grande Conservancy District (District). Access was also obtained from the City of Albuquerque Open Space Division for activities within the Rio Grande Valley State Park. All fish collections were conducted in accordance with Federal Fish and Wildlife Permit Number TE676811 and New Mexico Department of Game and Fish Authorization Number 3094 for Scientific and/or Educational Purposes. An Environmental Action Statement identifying a categorical exclusion to the National Environmental Policy Act was filed for the RGSM Health Study in June 2006. All consultation and interagency agreements between the BOR and the Service, and between the Service and NMED, the University of New Mexico, and USGS were completed by March 2008.

METHODS

Description of the Study Area and Sampling Sites

The study area was the MRG within the Rio Grande-Albuquerque Watershed (USGS Hydrologic Cataloging Unit 13020203; we term this the MRG Basin) in central New Mexico (Figure 1). The MRG Basin has a drainage area of approximately 8,298 square kilometers (km^2) (3,204 square miles (mi^2)) and in 2000, the land use land cover was approximately 59 percent rangeland, 23 percent forest, 7 percent agricultural, 6 percent urban, 3 percent barren, and less than 2 percent surface water or wetlands (NMED 2002). Within the study area, the District provides irrigation water for agricultural purposes in a narrow band of land along the MRG. The District provides water for flood irrigation of crops by diverting water from the MRG by a system of diversion dams and canals while directing return flows to the MRG through drainage ditches and interior and riverside drains (Langman and Anderholm 2004). The largest urban area in the MRG Basin is the City of Albuquerque with a population of 529,219 (U.S. Census Bureau 2009).

Sample Site Selection and Frequency of Sampling

The BOR (2005) recommended fish health sampling sites be selected in conjunction with the water quality monitoring program and include: 1) locations at or near the Angostura Dam, 2) near the mouth to about 0.4 kilometers (km) (0.25 miles (mi)) downstream of the Albuquerque Metropolitan Area Flood Control Authority (AMAFCA) North Diversion Channel; 3) near the mouth of the City of Albuquerque's Southside Water Reclamation Facility discharge; 4) near the Village of Los Lunas; 5) below the confluence with the Rio Puerco; and, 6) upstream of San Acacia Dam. The six sites selected for conducting sampling for the RGSM Health Study were in these areas (Table 1; Figure 2) and spanned over 171 km (106 mi) of the MRG from the Bosque del Apache National Wildlife Refuge, south of San Antonio, New Mexico, north to Bernalillo, New Mexico. Final site selection was based upon historical monitoring locations, access permissions, logistics, and personnel safety.

Sites selected for the RGSM Health Study (Table 1) included: Site 1, Rio Grande at Bernalillo, New Mexico, was upstream of the City of Albuquerque and was used as a reference site for data comparisons where appropriate (Figure 3). Site 2, Rio Grande at Alameda, New Mexico, was generally below main City of Albuquerque's urban stormwater runoff return through the AMAFCA North Diversion Channel (Figure 4). Site 3, Rio Grande at Los Padillas, New Mexico, was downstream of the City of Albuquerque; including the Southside Water Reclamation Facility discharge contained treated domestic and industrial wastewater (Figure 5). Site 4, Rio Grande at Los Lunas, New Mexico, was approximately 29 km (18 mi) downstream of the City of Albuquerque (Figure 6). Site 5, Rio Grande at La Joya, New Mexico, was approximately 8 km (5 mi) downstream of the confluence of the Rio Puerco (Figure 7). Site 6, Rio Grande near San Antonio, New Mexico, was approximately 6 km (4 mi) south of San Antonio (Figure 8) and downstream of the San Acacia Diversion Dam.

The RGSM Health Study was designed to collect fish health assessment, pathogen, genetic evaluations, and water quality parameters as a means to characterize the health of wild RGSM in relation to water quality measures in the Middle Rio Grande over two years, thus capturing variation longitudinally and across seasons. Sites were sampled during July 2006, October 2006, January 2007 and April 2007 (Year 1) and during October 2007, January 2008, April 2008, and July 2008 (Year 2). That is, eight sampling events were conducted quarterly over these two sample years during summer (July 2006 and 2008), autumn (October 2006 and 2007), winter (January 2007 and 2008) and spring (April 2007 and 2008). No sampling was conducted in July 2007. For quality assurance, a practice session of fish and water quality collection was conducted in June 2006.

Sample Site Characterization

River transect, fish collection, and water quality data were entered by hand onto pre-printed data forms or in field notebooks. Every effort was made to accurately document the conditions present during river transect characterization, fish collection, or water quality data collection events including documenting locations using a hand-held global positioning system (GPS) receiver, time of collection, characterizing general habitat type, and recording observations onto pre-printed forms or in notebooks. The GPS receivers (position accuracy plus or minus [±] 15 meters (m) (50 feet (ft); Garmin Model GPS V, Olathe, Kansas) were used to record the coordinates of fish collection efforts or water quality measurements and the coordinates were formatted using northing and easting (m) using the Universal Transverse Mercator, Zone 13, coordinate system, and the North American Datum of 1983. The coordinates were entered onto field forms by hand and verified through depiction of sampling site location on topographic images using desktop software ArcMap 10 (ArcGIS 10.0, ESRI, Redlands, California) and correcting any erroneous location coordinates noted and during data transferred into spreadsheets.

Where available, site photography was included of a 180 degree (or more) panorama made of individual digital still photographs taken with a Cybershot camera (Sony Corp USA, San Diego, California) and stitched together using Photostitch software (Canon Utilities, Version 3.1.10, Canon, Inc., Tokyo, Japan). Where possible, site photography was conducted during deployment of the continuous water quality monitoring probes at each site. Additional photography was collected of field or laboratory activities and was provided with the other chapters or appendix reports.

River Transects

Measurements of river water column depth, wetted width, and water velocity were made along a single cross-sectional channel transect at each sampling site and for each event (when possible). At each transect site, a tag line was set out along the cross section of the river channel and physical measurements were made in the water column approximately every 8 ft (2.4 m) along the tag line. Water column depth was measured using a top-set wading rod, marked in tenths of ft (or at approximately 3-centimeter (cm) increments). Mean column velocity was measured with a portable velocity meter (FLO-Mate Model 2000, Marsh McBirney, Loveland, Colorado) using the six-tenths depth method for water

depths less than 60 cm (2 ft) and the two point method for depths greater than 60 cm (2 ft). Depth and velocity data were averaged by sampling event and were used in calculations of ER, gross primary productivity, and for statistical analyses. However, we also compiled daily average discharge results at our sites as measured by the nearest upstream USGS gage station for 5-day periods around our fish and water quality data collections to characterize flows during our sampling events.

Occasionally, we were unable to wade safely across the MRG (as in April 2008). Or we required additional data to characterize river width, depth, and velocity at a site, for example, to determine ER rates and these values had to be estimated for missing data. To estimate river width, depth, and velocity at a site without empirical data, we used the average daily discharge data from the nearest upstream USGS gage station on the day of our fish collection. Also, using river transect data from our other sampling events at a site, and the width, length, and velocity measures collected by USGS at the nearest upstream gage station during the period of this study (2006-2008), we developed a series of equations to estimate river width, depth, and velocity based upon the average daily discharge volume reported by USGS during our data collection. These equations and the estimated values were identified below and were reported with our river transect results.

Collection of Rio Grande Silvery Minnow

At random, collections of fish were initiated upon arrival at each river site by 1-2 field teams (each with three or more members lead by fish biologists trained to identify fish species of the MRG). Fish were collected using flat seines (3 m wide x 1-2 m deep with 3.2-millimeter (mm) seine mesh and approximately one lead weight every 15 cm on the bottom line). RGSM were collected in a series of seine hauls events. Multiple attempts were necessary to collect sufficient numbers of fish. However, lack or fish or time restrictions occasionally prevented collection of adequate numbers of fish. Each seine haul containing fish was first processed to remove as much debris as practical, and fish species other than RGSM were returned to the stream, as were specimens of RGSM that were undersized (less than 30 mm total length [TL]) from the final RGSM collection. Up to 90 RGSM, greater than 30 mm TL, were targeted from each site (a river reach approximately 6 km or more in length) during each sampling event. Fish collected through seining were immediately identified by fishery biologists to species (e.g., using Mayden et al. 1992), enumerated, and those of sufficient length were placed in plastic buckets modified with fine mesh screens to allow river water to flow through it.

Once the RGSM were collected, along with adequate river water for their transport, the fish were immediately returned to a motor vehicle where they were transferred into plastic bags and transported to a laboratory for further analyses. Plastic transport bags were filled with river water to approximately two-thirds capacity (approximately 3 liters (L); 0.8 gallons); the remaining volume of the bag was inflated with pure oxygen and its opening sealed to prevent loss of the bag's contents. No additional salts or additives were added. Transport bags with fish and water were packed tight inside ice chests (without ice) to stabilize temperature and prevent sloshing. However, when ambient water temperatures were greater than 25°Celsius (C), small amounts of ice were added around

the bags inside of the chests and sealed. Average time between beginning of seine collections and arrival of fish at the laboratory was approximately 4 hours (hr).

Hatchery-produced RGSM have been stocked at various locations within the MRG (Service 2010). Each batch of hatchery-produced fish is distinguished by a unique Visible Implant Elastomer (VIE) tag attached inside the fish's body. The occurrence of hatchery-produced RGSM was noted during seine haul events. When marked RGSM were collected and observed during seine haul events, the unique attributes of the mark were noted (i.e., color and body location), and fish were collected and evaluated similar to wild RGSM.

Up to 90 RGSM (or more) were collected during each sample event, although some sites also did not yield sufficient numbers of fish to conduct further analyses. Up to 60 fish per site were surveyed for specific pathogens (i.e., bacteria, parasites and viruses) by the Service's Dexter Fish Health Unit (Woodland 2012). All RGSM collected in summer (July 2006 and 2008) for pathogen assessment also had tissues removed and that were provided to the Thomas F. Turner Laboratory of the University of New Mexico Museum, for genetic evaluations (Osborne and Turner 2009). As many as 30 RGSM per site were individually measured and examined for external and internal anomalies during a fish health assessment (Davis and Lusk 2012, Chapter 2). Up to 17 percent of the fish necropsied or their organs and tissues were submitted for further histological and histopathological examination (Papoulias et al. 2009, Appendix 4). As many as 30 fish (or more) per site of the partial body carcasses that remained after necropsy or pathogen assessment were wrapped in foil and frozen. Later, these individual fish were composited by site and date in chemically clean jars, and sent to the Trace Element Research Laboratory, College Station, Texas, for chemical analyses (Lusk 2012). Some of the remaining fish carcasses have also been analyzed for stable isotopes (Cook 2011). Remaining RGSM and tissues were archived at the University of New Mexico Museum for future use. These multiple coordinated analyses help to maximize the scientific information available from the sacrifice of these endangered fish.

Measuring Water Quality Parameters

Water Quality Monitoring during Fish Collection

All field meters used to measure water quality parameters were calibrated in the field (near sampling sites) according to the manufacturer's instructions prior to making measurements. During fish collections, water quality parameters were measured using a hand-held multiprobe meter (YSI Environmental, Model 556, Yellow Springs, Ohio) with a guarded, probe module. In shallow water, the probe module was submerged to just above substrate, while in deeper water, the probe module was submerged approximately to mid-depth of the water column. Stable readings were made by hand onto data forms of water temperature (in degrees Celsius [°C]), dissolved oxygen (in milligrams per liter [mg/l]), percent oxygen saturation, and specific conductivity (microSiemens per centimeter [µS/cm] at 25°C). Specific conductivity was measured using probes that contained automatic temperature compensation circuits to correct the

electrical conductance to 25°C. All data were transferred to Excel 2007 spreadsheets (Microsoft Corporation, Redmond, Washington), and data verified.

Continuous Water Quality Monitoring

The goals of the continuous water quality monitoring was to collect data and describe the range of water temperature, specific conductivity, pH, DO, and oxygen saturation at the sites before and after fish collection events. In addition, we used these continuous water quality measurements together with wetted width, average depth, and average velocities measured or estimated at a river transect to estimate GPP and ER. The focus of this continuous monitoring was on the characteristics and range of water quality parameters and derivation of GPP and ER at six locations by season and sampling year as well as to compare with average daily discharge or suspended sediment concentrations as measured by USGS at nearby gage stations. Another objective of this monitoring was to better identify water quality parameters exhibiting degradation within a reach to help guide RGSM and water quality management efforts.

Sample site selections for continuous water quality monitoring were as described above. Continuous monitoring of water quality was made at or near the transect location at each site. The continuous water-quality monitoring devices were deployed at least 1 day before until at least 2 days after fish collection events and often for 5 days in total. Continuous water quality monitoring was conducted at 15-minute intervals for at least 24 hr using one of four multi-parameter "Sonde" devices (Datasonde or Minisonde Models 4a, Hydrolab Corporation, Austin, Texas). These Sondes used a four-parameter probe monitoring system, which collected water temperature, electrical conductivity, DO, oxygen saturation, and pH data. These Sondes were outfitted with a temperature-compensated, polarographic membrane-type oxygen sensor probes and used a standard membrane in the determination of DO. Water temperature and DO were also measured at 15-minute intervals for at least 24 hr using one of three, non-vented, continuous monitoring multiparameter "Troll" devices (Troll Model 9500, In-Situ Inc., Fort Collins, Colorado). These Trolls were outfitted with a rugged, optical, fluorescence-quenching sensor probes to determine DO. These sensors employ a light-emitting diode to provide incident light that excites the oxygen-sensitive substrate of the sensor. The magnitude of luminescence is measured and is inversely proportional to the DO concentration in the water. Using both these types of oxygen probes allowed for comparison of the two types of methods of DO measurement. However, all DO data measured by different probe types were combined for each site. Prior to deployment, routine calibration and maintenance according to the manufacturer's instructions was conducted on each probe.

The continuous water quality monitoring devices (up to two per site, one of each type) were installed in perforated plastic pipes that were suspended, mid-water column, by cables fastened between iron posts driven into the streambed at the center of flow determined by wading across to estimate the deepest location (i.e., thalweg) accessible at each site. In addition to serial numbers, proper names were given to each of the different probes (Trolls and Sondes) to better track their deployment and retrieval as well as during calibration, data retrieval, and data organization.

Data Analysis

Water quality data were stored on internal memory of the continuous monitoring devices for later downloading. Data were then imported into spreadsheets. Data were amended with date column, reviewed for deployment date and time, removal date and time, notations were removed, and data were plotted. Anomalous data, such as negative values, or values measured when probes were not in water, or when probe had been placed into a calibration solution were discarded.

Data were imported into Excel spreadsheets or imported and analyzed using the statistical software Statistica (version 9.0, StatSoft, Tulsa, Oklahoma) or database software (Microsoft Office Access 2007, Microsoft Corporation, Redmond, Washington) on a desktop computer. Prior to final statistical analysis, the assumptions of normality and equal variance were formally tested by the Shapiro-Wilks test and Levene's test, respectively (Statsoft 2011). Data that did not meet these assumptions were transformed to their natural logarithms and retested, such as for a one-way analysis of variance (ANOVA) or students' t-test (Statsoft 2011). If the natural log-transformation did not satisfy the assumptions, data were transformed to ranks and a Kruskal-Wallis and median test was applied to test the ranks (Statsoft 2011). Other parametric and nonparametric statistical tests were also employed and were so indicated in the text. Statistical significance probability (p) was set at p less than or equal to 0.05 for all statistical tests.

In some cases, continuous monitoring devices were smothered by sediment and were so noted upon their removal. Smothering of devices by sediment could have occurred anytime between deployment and discovery during their removal or during fish collections. After review of all data, those dissolved oxygen saturation data less than 50 percent oxygen saturation were considered suspect from those water quality devices that were found smothered. Therefore, all data (i.e., pH, temperature, dissolved oxygen content and saturation, specific conductivity measures) from those devices identified as smothered were flagged and censored from subsequent analyses and were so noted. Continuous monitoring data were summarized and qualitatively evaluated for comparisons by site, season, or sample year with other observations. General water quality was also assessed by comparing results to water quality standards (NMWQCC 2000; 20.6.1 New Mexico Annotated Code (NMAC)) or other guidelines as cited.

Derivation of Gross Primary Productivity and Ecosystem Respiration

We measured the rate of oxygen change in water over time with the continuous water quality monitoring probes to determine GPP and ER rates at each site that was associated with fish sampling. GPP and ER were determined using an open-system, single-station approach (Owens et al. 1974, Bott 1996). GPP and ER together, are referred to as "whole stream metabolism" (Bott 1996). Oxygen dissolved in water tends to fluctuate on a diurnal (24-hr) basis based on changes in temperature, stream mixing, barometric pressure and aquatic plant productivity. Together, processes like respiration, photosynthesis, water warming and cooling, or aeration typically gives a sinusoidal, diel-

pattern of DO and oxygen saturation that has minima in the early morning and maxima in the late afternoon (Odum 1956). Conversely, the observed oxygen gain and loss patterns from its measurement in stream waters can be used to calculate the component rates of primary production and ER (Odum 1956). Net primary productivity is the rate of formation of organic carbon (matter) from water and inorganic carbon by photosynthesizing organisms, which represents the conversion of solar energy to fixed energy that forms the base of food webs (Bott 1996). At night, some of this fixed energy is lost through plant respiration (i.e., the chemical processes by which plant sugars and starches are converted to energy through oxidation back into inorganic carbon and water). That portion of the fixed energy that remains and is stored as plant biomass is termed net primary productivity. Oxidative processes that may occur in sediment or the water column and respiration by bacteria, invertebrates, fungi, fish, and other aquatic organisms are included in the calculation of ER rates. The total (ER plus net primary productivity) is termed GPP. ER rates, GPP, and gas diffusion interact to produce the daily curve of oxygen change in the segment of flowing water that we measured using the continuous monitoring probes.

We used the continuous monitoring of temperature and dissolved oxygen over 24 hr to relate the rate of GPP, ER, and oxygen gas exchange with the atmosphere, assuming that groundwater inputs were negligible. Groundwater inputs of low DO into the MRG might not be negligible (see Mills 2003), however, we were unable identify methods to detect the relative contribution of groundwater on surface water oxygen content. Oxygen saturation often increases during daylight hours when photosynthesis is occurring and decreases at night when respiration continues and photosynthesis ceases. We used the DO and temperature measured at a site, and barometric pressure at calibration, to calculate the DO expected at saturation for a location using Equation 3 from Munson et al. (2004). From this, we calculated the amount of surplus or deficit oxygen saturation during each DO measurement. River transect characteristics of each site (i.e., average depth and velocity) were also used with the amount of surplus or deficit oxygen saturation to determine the oxygen exchange coefficient according to Owens et al. (1974) and Bott (1996). The area under the reaeration-corrected rate of oxygen change as a curve on standardized plots above a line drawn through the predawn to post dusk points was determined using a roller-type, digital planimeter (Placom Model KP90N, Tokyo, Japan) to estimate daily GPP. Water quality measured during the night (as defined as "civil twilight" between sunset and sunrise). Civil twilight was used as the limit at which illumination was sufficient for terrestrial objects to be clearly distinguished and was assumed to represent the period with most of the photosynthetic activity.

Division of the oxygen exchange rate by 24 hr converts the daily rate to an hourly rate, and hourly rates during civil twilight were averaged to determine average hourly nighttime respiration rates (Bott 1996). ER was then determined by multiplying the average hourly nighttime respiration rate by 24-hr. Whole stream metabolism was estimated from the difference between GPP and ER for those periods where both were measured. However, only GPP and ER rates and their ratios were statistically summarized, compared, and used in subsequent analyses.

RESULTS

Sampling Site Location and Characterization

Location of fish and water quality sampling events are depicted on Figures 3 to 8. Graphs of average daily discharge measured at the nearest upstream USGS gage that depict the fish collection and the deployment or retrieval of continuous water quality monitoring devices are on Figures 9-48 (Appendix 1A). Riverscape photography was used to characterize sampling sites and was provided in Plates 1 to 44 (Appendix 1B).

River Transects

Overall average wetted width at site transects was 257 m (880 ft), with Site 3 being the widest sampled (Table 2). Overall average depth at site transects was 0.45 m (1.5 ft). Site 1 was the deepest on average (0.52 m (1.7 ft)); however, Site 5 was the deepest (0.87 m (2.8 ft)) in April 2008, when stream discharge was measured over 100 cubic meters per second (m^3s^{-1}; 3010 cubic feet per second (ft^3s^{-1})). Overall average velocity at site transects was 0.53 m^3s^{-1} (1.75 ft^3s^{-1}). The swiftest velocity was measured at Site 1 during April 2008, and slowest was measured at Site 4 during July 2006, when the site had begun drying (Table 2). Low river discharge and river drying in July 2006 resulted in the low average depths and velocities at Site 4 to Site 6 (Table 2). Additionally, low river discharge in October 2007 also resulted in low average depth at Site 5 (Table 2).

Fish Collection

Up to 90 RGSM were collected during each sampling event, although we were unable to collect sufficient RGSM fish to conduct all fish health and pathogen analyses at some sites (Table 3). In total, 3,170 RGSM were collected in 957 successful seine hauls ranging from 1 to 56 RGSM per seine haul. Average catch (and standard deviation (SD)) was 3.3 ± 5.0 per seine haul. More RGSM were collected in Year 2 (1,932) than in Year 1 (1,238) and while more seine hauls were conducted in Year 2 (520), the catch rate was also better in Year 2 (3.5 ± 5.8) than Year 1 (2.8 ± 3.5) (Table 3). More RGSM were caught in summer (990) than in winter (752), and along the river's edge (36 percent) or in small channels (36 percent) than in the other habitat types sampled.

Water Quality during Fish Collection

All field water quality measurements were collected during the day only. Water quality measurements were collected only at 90 percent of the RGSM collections due to occasional equipment failures and data omissions. RGSM were collected in a wide range of water temperature (0.6 to 34.6 °C), dissolved oxygen (3.7 to 15.8 mg/L), pH (5.6-9.5) and specific conductivity (232-1,083 µS/cm) (Table 3 and 4). During RGSM capture, overall water temperatures measured were warmer (Kruskal-Wallis ANOVA, $H(1,896)=53.41$, $p<0.05$) during Year 1 (14.0 °C) than Year 2 (11.7 °C). There was a significant negative correlation (Kendall Tau = -0.13, $p<0.5$) between specific conductivity and the number of RGSM collected per seine haul in Year 2. We attributed

this relationship to the high catch rate of RGSM at Site 1 and Site 2 during Year 2 (Table 3). No other significant relationships were found between water quality measures and the number of RGSM captured during successful seine hauls.

Continuous Water Quality Monitoring

Over 30,000 observations of continuous water quality monitoring data are provided in Appendix 1C (Tables 5.1 to 5.82). As water quality data were collected night and day, we used these continuous water quality monitoring data to summarize the site conditions during this study. Water quality measured during the night was indicated in Appendix 1C by gray shading. Occasionally, continuous water quality monitoring devices were found smothered by sediment and were notated in Appendix 1C. Except as noted below, all water quality measures were censored from statistical analyses and interpretation whenever the oxygen saturation was less than 50 percent (a value we associated with the onset of sedimentation and fouling of the water quality monitoring devices). Summary statistics of these data for temperature, specific conductivity, pH, DO, and oxygen saturation by probe type, site and season are provided in Tables 6 to 10. Generally, temperatures were similar as measured by the different probe types, but DO was often lower when measured using a membrane-type sensors on the Sondes.

Temperature

The average water temperature for the Rio Grande during this study was 12.9°C with the range of average site temperatures falling between 2.6 °C in the winter and 26.0 °C in the summer (Table 6). Water temperatures showed the greatest variability in the summer and fall, and were least variable in the winter (Table 6). Site temperatures were colder in Year 2 (11.9±6.7°C) compared to Year 1(14.0±7.3°C) (Kruskal-Wallis $H(1, 30{,}104) = 872.7$ $p < 0.001$). In Year 1, Site 6 was significantly colder (11.7±8.5 °C) and Site 2 was significantly warmer (15.6±6.5 °C) in ranked temperatures than at the other sites (Kruskal-Wallis $H(5, 14{,}163) = 331.6$, $p < 0.001$). In Year 2, Site 1 (11.0±6.8 °C) and Site 6 (11.5±7.2 °C) were significantly colder than at Sites 2, 3, and 4, while Site 2 was significantly warmer (13.2±7.2 °C) in ranked temperatures than at the other sites (Kruskal-Wallis $H(5, 15{,}941) = 180.0$, $p < 0.001$). Site 1, the Rio Grande at Bernalillo, New Mexico, was generally the coldest site, on average, during spring, summer, and winter. Summer temperatures were highest at all sites, with temperatures greater than 38 °C on July 17, 2006, at Site 4, the Rio Grande at Los Lunas, New Mexico, during a period of river drying.

Specific Conductivity

The average specific conductivity for the Rio Grande during this study was 305 µS/cm with the range of average site conductivities falling between 171 and 605 µS/cm. Specific conductivity showed the greatest variability in Fall 2006 at Site 2 and Site 3, and was least variable at Site 1 (Table 7). Conductivity generally increased from upstream sites to downstream sites, and was greater at sites in Year 2 (329±113 µS/cm) compared to Year 1 (299±113 µS/cm) (Kruskal-Wallis $H(1,12{,}239) = 87.5$, $p < 0.001$).

pH

The overall site average pH of the Rio Grande was 8.2 with the range of average site pH falling between 7.7 and 8.8 (Table 8). The greatest variability in pH was at Site 1 (pH 7.7 to 9.2), and at Site 2 (pH 7.3 to 9.0) (Table 8). The pH was lowest at all sites during the summer, with the exception of Site 3. The least variable pH was measured at Site 3. The average pH (8.0) was generally the lowest at Site 3 compared to other sites measured (Table 8). Average pH was significantly higher (Kruskal-Wallis $H(1,13,978) = 155.6$, $p < 0.001$) at sites measured in Year 2 (8.3±0.3) compared with those in Year 1 (8.2±0.2).

Dissolved Oxygen (DO)

DO concentrations showed the greatest variation in the spring and least variation in the winter (Table 9). The average DO concentration for the Rio Grande during this study was 8.1 mg/L with the range of average site concentrations between 4.1 and 11.6 mg/L (Table 9). The highest DO concentrations were measured at Site 1 in January 2008. The lowest DO concentrations were measured at Site 6, in July 2006. Site 1 was at the highest elevation (of the sites measured) and had low water temperatures, and Site 6 was at the lowest elevation and had some of the highest water temperatures. A decreasing trend in DO from sites upstream (at lower atmospheric pressure and generally colder in temperature) to downstream sites would be expected (Benson and Krause 1980). DO concentrations were significantly and inversely correlated with temperature (Spearman Rank $r = -0.78$, $p<0.05$). We found that a linear relationship between temperature and DO concentration for the sites in the MRG that was best described by the equation: DO (mg/L) = 10.7798 - 0.2106 * Water Temperature (in Celsius). No additional analyses of these DO data were conducted as data were censored when continuous water quality monitoring probes were considered smothered with sediment (i.e., less than 50 percent oxygen saturation).

Oxygen Saturation

Oxygen saturation showed the greatest variation in the summer and least variation in the winter (Table 10). The average oxygen saturation for sites in MRG during this study was 89 percent with the range of average site concentrations between 87 and 94 percent (Table 10). The highest oxygen saturation was measured at Site 4, in July 2007. The lowest oxygen saturations were measured whenever sediment began to smother the oxygen probes of the water quality monitoring devices stationed at various sites. No additional analyses of these oxygen saturation data were conducted as the data were censored when continuous water quality monitoring probes were considered smothered with sediment (i.e., less than 50 percent oxygen saturation).

Ecosystem Respiration (ER)

The average 24-hr ER rate for sites on the MRG during this study was -18.2 grams of oxygen per square meter per day ($gO_2/m^2/day$) with the range of average site respiration

between -9.6 and -20.6 gO_2/m^2/day (Table 11). For all sites, the highest average site respiration was during fall (-20.7 gO_2/m^2/day), and it was lowest during winter (-9.4 gO_2/m^2/day). Site 1 had the most variation in respiration rates (-15.7±22.5 gO_2/m^2/day). During both sample years, Site 1 and Site 6 had significantly lower respiration rates compared with other sites (Kruskal-Wallis H (5, 382) =29.5, $p<0.0001$).

Gross Primary Productivity (GPP)

No useable GPP data were available from several sites in Spring 2007 and Summer 2008 (Table 12). The average GPP for the Rio Grande during this study was 3.5 gO_2/m^2/day with the range of average GPP between 1.8 and 4.8 gO_2/m^2/day (Table 12). For all sites, the lowest average GPP was in spring (3.0±2.5 gO_2/m^2/day), and it was highest in summer (4.1±1.9 gO_2/m^2/day). Site 2 had the highest GPP (17.6 gO_2/m^2/day) and highest variation. Site 5 had the lowest average GPP (1.8 gO_2/m^2/day) and lowest variation. GPP for all sites was greater in Year 2 (4.4±3.0 gO_2/m^2/day) than in Year 1(2.5±1.9 gO_2/m^2/day) (Kruskal-Wallis H (1, 223)=39.3, $p <0.0001$).

PR Ratio

Odum (1956) used the ratio of GPP to ER (the PR ratio) to classify streams as heterotrophic or autotrophic. Streams are heterotrophic (organic matter is imported into the stream) if the PR ratio is less than 1, or autotrophic (organic matter is created in the stream from inorganic compounds and sunlight) if the PR ratio is greater than one.

The average PR ratio for sites on the MRG was 0.1 with average PR ratios for sites ranging from -0.5 at Site 6 to 1.9 at Site 1 (Table 13). For all sites, the lowest average PR ratio was in spring (-1.1), and was highest in winter (1.0). PR ratios were similar by sample year (Kruskal-Wallis H (1, 223) =2.2, $p =0.13$) and season (Kruskal-Wallis H (3, 223) =7.6, $p =0.06$). However, PR ratios were greater at Site 3 and Site 4 than Site 6 in Year 1 (Kruskal-Wallis H (5, 105) =16.6, $p =0.005$), and PR ratios were greater at Site 5 than Site 6 in Year 2 (Kruskal-Wallis H (5, 118) =12.4, $p =0.03$).

DISCUSSION

Temperature

Temperature affects the density of water, the solubility of its constituents (such as oxygen), pH, specific conductivity, the rate of chemical reactions, and biological activity in water (Radtke et al. 2003). Both RGSM hatching and larval development are affected by high temperatures (Platania 2000). Oxygen saturation is also decreased by higher temperatures. During low flows, flow tends to be more stable with reduced stream power, and conditions in pool habitats that have near zero velocity are often more pronounced and have an elevated heating capacity (Service 1994, 2003). Small changes in water temperature are known to have considerable effects on freshwater fishes by affecting a variety of life history, behavioral, and physiological aspects (Morgan et al. 2001; Carveth et al. 2006). Alterations in the temperature regime from natural background conditions negatively affect population viability, when considered at the scale of the watershed or individual stream (McCullough 1999).

Buhl (2007) reported the median 24-hr lethal temperature for 90-day post-hatch RGSM was 36.1°C. Temperatures in excess of this median lethal temperature (up to 38.4°C) were observed 27 times during July 17 to 20, 2006, at Site 4. Temperatures were observed 10 times (up to 37.0 °C) on July 19, 2006, at Site 6. Low flows were reported at both of these sites (Table 2). However, RGSM were found at both sites (some were collected for health assessments and they were found in poor condition; Woodland 2012; Papoulias et al. 2009; Davis and Lusk 2012). The relationship between water temperature measured near the deepest flow (thalweg) and the temperature at the edges where the water is shallow is uncertain. Both Abeyta and Lusk (2004a) and SWCA (2010) have described water temperatures at the river's edge, as measured along transects, or in backwaters and side channel habitats as varying widely (0 to 14 °C) from water temperatures measured near the area of deepest stream flow. While we would expect that water temperatures in edge habitats near those where we measured elevated water temperatures may have been higher than 36.1°C for some period of time. There was not enough information to predict the range of water temperatures in the edge habitats of a river near our measurements of water temperature at the river's thalweg.

The temperature criterion for the main stem of the Rio Grande near these sites is 32.2 °C or less, in any single sample (NMWQCC 2000). Temperatures measured exceeded the 32.2 °C temperature criteria 93 times at Site 2 and 51 times at Site 6 during summer 2006. There are exceptions to the water temperature criterion that include "unusually high ambient air temperatures" (20.6.4.13.I. NMAC) or "when changes in temperature . . . are attributable to . . . the reasonable operation of irrigation and flood control facilities that are not subject to federal or state water pollution control permitting" (20.6.4.11.I.(2) NMAC). In July 2006, the maximum daily ambient air temperature was 40 °C and was not considered unusually high (http://weather-warehouse.com/WeatherHistory/PastWeatherData_BosqueDelApache_Socorro_NM_July.html). Additionally, the effect of operations of the Isleta Diversion Dam (an irrigation

facility) on Site 2 or downstream of the operations of the San Acacia Diversion Dam (an irrigation facility) on Site 6 water temperatures have not been assessed. If the reasonable operation of these irrigation facilities contributed toward water temperatures in excess of the lethal levels observed at these two sites, then exceptions to the temperature criteria in the New Mexico water quality standards might not be protective of RGSM.

Specific Conductivity

Electrical conductivity is a measure of the capacity of water to conduct an electrical current and is a function of the types and quantities of dissolved substances in water (Radtke et al. 2005). As concentrations of dissolved ions increase, specific conductivity of the water also increases. Electrical conductivity measurements can be used to estimate total dissolved solids (TDS) in water by multiplying specific conductivity by 0.584 and adding 22.1 (USDI 1998).

A pulse of water with high conductivity was measured at Site 2 (1,027 µS/cm; compared with the average with this site of 250 µS/cm), and at Site 3 (974 µS/cm versus the average for this site of 332 µS/cm) on October 10, 2006 (Figure 49). The daily discharge reported for the Rio Grande at San Felipe (USGS Gage 08319000), the Jemez River (USGS Gage 08329000), and the North Diversion Channel (USGS Gage 08329900) (Figure 4.2.5.3; Appendix 1B), had all increased during this time period suggesting their contributions influenced the specific conductivity measure at Site 2 during those days. The pulse of high conductivity water travelled approximately 40 km (25 mi) at a rate of over 1.3 ms^{-1} (3 mi hr^{-1}) as peak conductivity was measured at 2 p.m. on October 10, 2006, at Site 2, and 8 hr later at Site 3. Elevated conductivity was then measured for several days thereafter (Figure 49).

Just prior to this peak in conductivity, a low conductivity pulse was also measured and was associated with colder water temperatures (Table 5.10; Appendix 1C). Precipitation, because of its high content of carbon dioxide, normally has a low pH and low mineral content (Hynes 1970). During this time period, precipitation was reported at the Albuquerque International Airport in 2006 on October 7 (1.0 mm), October 8 (3.3 mm), and October 9 (31.2 mm) (NOAA 2006) during the period the low conductivity pulse was measured. Precipitation was also reported in the foothills east of Albuquerque in 2006 on October 8 (2.5 mm), October 9 (14.7 mm), and October 10 (25.4 mm) (NOAA 2006). Precipitation was only reported at the Jemez Dam in 2006 on October 10 (35.6 mm) (NOAA 2006). In response to heavy precipitation, a large amount of stormwater with a low mineral content can directly enter a river without have reached equilibrium with soils, whereas, after exposure to soils over time, stormwater runoff is likely to increase in TDS content (and neutralize the pH) as water passes over and percolates through the soil and dissolves calcium ions and other mineral salts. Therefore, we identified the stormwater runoff through the North Diversion Channel by the initial pulse of cold-water temperature with low conductivity. Following that pulse, the Jemez River, with its elevated conductivity, appeared to have contributed to the conductivity that we measured at Site 2 in October 2006. Pulses of elevated conductivity have been occasionally reported in the Rio Grande below San Marcial, New Mexico, by Hem (1992) and Moore

and Anderholm (2002). Variations in conductivity measured in the Rio Grande have also been associated with stormwater discharges from the Albuquerque metropolitan area by way of the North Diversion Channel (Kelly and Romero 2003; Kelly et al. 2006).

The median conductivity of 250 µS/cm at Site 2 would equate to approximately 168 mg/L TDS, whereas the peak pulse of conductivity measured at Site 2 on October 10, 2006, at 1,027 µS/cm, would approximate a TDS of approximately 622 mg/L. A TDS of 622 mg/L was not considered toxic to fish (USDI 1998). Toxicity due to TDS can result from disruption of organisms' osmotic regulation processes, decreases in bioavailability of essential elements, increases in availability of heavy metal ions, increases in particularly harmful ions, changes in ionic composition, absence of chemical constituents that offset impacts of harmful ions, a combination of the above, or other as yet unknown mechanisms (U.S. Environmental Protection Agency (USEPA) 2010). Increased TDS tends to cause shifts in aquatic community composition rather than acute mortality (USEPA 2010).

Information on toxicity of salinity or TDS on RGSM is generally lacking, presenting a substantial gap in predicting effects. Hoagstrom (2009) described the extirpation of RGSM from portions of the Pecos River with average TDS greater than 4,400 to 10,700 mg/L. Ostrand and Wilde (2001) described concentrations of salinity lethal to 50 percent of a population of plains minnow (*Hybognathus placitus*) as high as 16,000 ± 1,940 mg/L). However, Hoagstrom et al. (2010) described plains minnow as generally more environmentally tolerant than RGSM. Additionally, Cowley et al. (2009) reported that four 'practical salinity units' were lethal to approximately 50 percent of RGSM eggs. However, the use of a practical salinity scale by Cowley et al. (2009), does not result in salinity units that are basic to the fields of chemistry and physics, and therefore, cannot be easily interpreted or compared to other sites with conductivity measurements or TDS in units of milligrams solute per liter without additional information on ion composition (United National Educational, Scientific and Cultural Organization 1981, 1985).

The composition of the ions that make up TDS (e.g., sodium, calcium, potassium, sulfate, and other common ions) can make substantial differences in toxicity to fish and invertebrates (Mount et al. 1997; Soucek et al. 2011). For example, Mount et al. (1997) identified the range of sodium chloride (NaCl) concentrations in 48 hr that were lethal to 50 percent of fathead minnows was 6,090 to 7,070 mg/L, and to its invertebrate prey (*Daphnia magna*), which ranged from 3,790 to 5,740 mg/L. Whereas the range of sodium chloride and sodium bicarbonate mixtures that were lethal to 50 percent of fathead minnows was 2,330 to 5,250 mg/L, and to its invertebrate prey, ranged from 2,830 to 3,080 mg/L. Using these toxicity results, the average ratio of fathead minnow-to-invertebrate toxicity test results was 1.35. This suggests that mixtures of different ions can be additive in their toxicity to fish and their prey. Therefore, estimates of acute toxicity to 50 percent of a test species, or using single ions, may not be adequate to characterize the long-term effects of TDS to RGSM and additional study is warranted.

Soucek et al. (2011) described the acute toxicity of TDS to invertebrates (*Ceriodaphnia dubia*) based on a relationship with hardness. Using the Soucek et al (2011) TDS toxicity

relationship, and an average hardness of 141 mg/L in the Rio Grande at Isleta (Buhl 2002), we calculated the average TDS acutely lethal to 50 percent of invertebrates at 9,160 mg/L. Then, using an acute-to-chronic ratio for chlorides to invertebrates of 3.187 (Stephan 2009), and a safety factor of two to account for mixtures (above), we determined that the average chronic toxicity of TDS to invertebrates would be 1,437 mg/L. Assuming the ratio of fathead minnow-to-invertebrates of 1.35 was valid for extrapolating from this invertebrate toxicity estimate, then the average chronic toxicity of TDS to fathead minnow would begin above 1,940 mg/L. Therefore, assuming these relationships are an appropriate surrogate effects analysis for RGSM, then the pulse of TDS of approximately 622 mg/L at Site 2, on October 10, 2006, did not appear to adversely affect fathead minnow (1,940 mg/L), or exceed the monthly average TDS criterion of 1,500 mg/L in the MRG (20.6.4.105 NMAC).

pH

The pH is a measure of the concentration of hydrogen ions in the water. More specifically, pH is a measure that represents the negative base-10 logarithm of hydrogen-ion activity of a solution, in moles per liter (Radtke et al. 2003). Solutions having a pH below 7 are described as acidic, and solutions with a pH greater than 7 are described as basic or alkaline. Plant photosynthesis has also been indicated in raising pH, either by removing calcium content or by increasing activity of hydroxyl ions (Hynes 1970).

Elevated pH was measured at Site 1 and occurred every night between 6:30 p.m. and 6 a.m., during January 26 to January 31, 2008. Elevated pH was most frequently observed on January 27, 2008 and was its highest (pH 9.2) at 1:30 a.m. (Appendix 1C, Table 5.52). That pH increased only during nighttime was unusual, as ER activities (at night) can often release carbon dioxide, which tends to decrease pH, whereas increased primary productivity can increase the hydroxyl ions, which tends to increase pH (Hem 1992). The elevated pH observed at Site 1 occurred when DO concentrations were at their highest during the day. The reason for elevated pH measured at Site 1 during winter is unknown.

Elevated pH was also measured at Site 2 on October 9, 2006, during stormwater runoff that corresponded to the pulse of low conductivity water from the North Diversion Channel, just prior to a peak of elevated conductivity from the Jemez River (described above; Figure 49). The sudden inflow of stormwater to Site 2 in October 2006, may have affected the equilibria of both pH and conductivity in the water column. It is also possible that stormwater runoff (initial pulses of rainwater with low conductivity) did not have the buffering capacity to moderate the changes in pH during these events. Elevated pH measured at Site 2, in October 2006, was not also associated with an increase in DO.

The pH was lowest at all sites during the summer, with the exception of Site 3. The average pH (8.0) was generally the lowest at Site 3 compared to other sites measured. Passell et al. (2001, 2007) also reported that average pH was lowest (7.9) in the Rio Grande at Isleta, New Mexico (just downstream of Site 3) compared to other sites they measured. Wilcox (1997) and Passell et al. (2001, 2007) attributed the drop in pH at the

Rio Grande near Isleta, to the contribution of the treated sewage (which had a lower pH < 7.8) discharged from the Southside Water Reclamation Facility near Albuquerque.

The pH water quality criterion for the main stem Rio Grande in this area (Segments 20.6.105 and 20.6.106 NMAC) is "pH within the range of 6.6 to 9.0 or less, in any single sample." Exceedances of this pH criterion were observed 117 times, mainly at night Site 1, during the night in January 2008. Many biological effects to pH changes are often associated with acidic conditions (pH < 7; see Thurston et al. 1979). However, elevated pH can also cause direct physical damage to fish skin, gills and eyes, and an inability of fish to excrete metabolic wastes (especially when elevated pH occurs in conjunction with exposure to ammonia), or death (Calabrese 1969, Thurston et al. 1979; USEPA 1995). However, some fish species (other than RGSM) have survived over six months at an elevated pH (greater than pH 9, but less than pH 9.5; McCarraher and Thomas 1968; Table 1). McCarraher and Thomas (1968, Table 2) reported that fish exposed to pH 9.2 or greater survived less than six months. Research would be necessary to determine if elevated pH measured in the Rio Grande is associated with adverse effects to RGSM.

Oxygen Saturation and DO

Oxygen is essential to all aerobic aquatic organisms (Davis 1975; BCME 1997). Oxygen solubility, or the amount of DO in the water column is governed by many factors including atmospheric and hydrostatic pressure, temperature, turbulence, salinity, turbulence, groundwater upwelling, ice cover, and biological processes such as the oxygen byproducts of photosynthesis by aquatic plants (Odum 1956; Benson and Krause 1980; Bott 1996; Wagner et al. 2006). The capacity of water to hold oxygen in solution is inversely proportional to the water temperature (Benson and Krause 1980). Increased water temperature lowers the concentration of DO at saturation. Saturation is the maximum quantity of DO that water, in equilibrium with the atmosphere, can contain at a given temperature and pressure (i.e., based on the elevation of the water body). As a result, even when DO decreases as water temperature increases, and increases with increased atmospheric pressure, relative oxygen saturation can be compared more easily across sites and seasons.

DO may also be depleted by oxidation reactions or by biological and chemical processes that also contain dissolved, suspended, or precipitated organic matter or by other oxygen-demanding substances (Odum 1956; Hem 1992; Bott 1996). Diurnal fluctuations in DO concentrations can result from photosynthesis in excess of respiration as a source of oxygen during the day. At night, when photosynthesis ceases, respiration continues to consume oxygen and reduces the DO concentrations in the water column (Ignjatovic 1968; Bott 1996). Oxygen depletion is usually associated with excessive temperature, heavy growth of aquatic plants, algal blooms, or high concentrations of organic matter and nutrients (USEPA 1995). Oxygen depletions in the MRG have been associated with stormwater discharges from tributaries and urban areas, and floodplains inundation with high concentrations of organic matter (Abeyta and Lusk 2004b; Valett et al. 2005; Van Horn 2008; DBS&A 2009, Service 2011).

Fish may compensate for low DO conditions by behavioral responses, such as increased use of aquatic surface respiration, changes in activity level or habitat use, and reflexive avoidance behaviors, though these activities are known to come at a higher energy cost (Davis 1975; Kramer 1987; BCME 1997). Below some threshold oxygen saturation, fish will be expending energy to maintain homeostasis and some degree of physiological stress will occur (Davis 1975; Heath 1995). Ventilation rates are often increased, reduced feeding and movement activity are decreased and increased glycolysis and cortisol release can be induced even by short-term low DO conditions (Kramer 1987; Heath 1995; BCME 1997). Additionally, low DO conditions may also cause a wide range of chronic effects and behavioral responses in fish (Downing and Merkens 1957; Hughes 1973; Kramer 1987; Breitburg 1992). For example, chronic toxic effects have been reported in fish at concentrations that range from four to seven times those concentrations reported lethal the 50 percent of a test population (Davis 1975; Matthews and Hill 1977; Matthews and Maness 1979; USEPA 1995; Balfour 2000).

Buhl (2007, 2011) reported 50 percent mortality of a test population of adult RGSM exposed to water containing DO from 0.8 mg/L (6.7 to 13.2 percent oxygen saturation) for a 3-hr exposure without allowing RGSM to access the water surface (and respiring the thin layer of DO at the air-water interface). Buhl (2011) reported that the highest DO concentration observed without acute mortality to larval RGSM (i.e., those that had no access to the water surface) was 2.4 mg/L (i.e., 29.8 percent saturation). Buhl (2011) reported that the highest DO concentration observed without acute mortality to adult RGSM (i.e., those that had no surface access) was 4.4 mg/L (54.3 percent saturation).

We assumed that RGSM in water of DO less than or equal to 4.4 mg/L (i.e., 54.3 percent saturation), will begin to experience adverse effects such as changes in ventilation rates, increased surface water respiration, lack of feeding activity, metabolism changes, increased risk of predation (due to fish condition or position), and some (approximately 10 percent, see Buhl 2011) will begin to experience mortality. We also assumed that DO concentrations at or below 2.4 mg/L (29.8 percent oxygen saturation) are lethal to larval RGSM. As temperature and pressure, as well as other factors (above) can affect the solubility of DO in water, in the MRG (as compared to the temperature and pressure reported by Buhl 2011); we used oxygen saturation values (of 29.8 and 54.3 percent respectively) to describe the onset of acute adverse effects to larval and adult RGSM. Therefore, oxygen saturations (i.e., censored values) we measured at MRG sites were less than 54.3 percent saturation (adult RGSM adverse effect level) for approximately 67 days (17.9 percent of the time) and less than 29.8 percent saturation (larval RGSM adverse effect level) for approximately 33 days (8.8 percent of the time) in cumulative duration during the 374 days of continuous monitoring during 2006 to 2008. However, it is possible, that even though we used only censored oxygen saturation data, that some of the low oxygen saturation values measured were nonetheless associated with the *onset* of sediment fouling of the oxygen sensors. Sediment as oxygen demand is described below.

The majority of low oxygen saturation measurements were observed in spring (38 percent), during high runoff events and they occurred least in winter (8 percent). We also compared our daily oxygen saturation values with the average daily discharge as

measured by USGS (at the nearest gages), and found a significant linear relationship, that being: lnDischarge (in cubic feet per second) = 106.7004 - 1.3797*oxygen saturation ($F(1,77)=5.6$, $r=-0.26$, $p=0.02$). This suggested that higher flow events tended to reduce oxygen saturation measured at these sites, perhaps through the suspension of sediment in the water column. Kreutzberger et al. (1980) reported that low DO in the Milwaukee River was attributable to sediment oxygen demand (SOD) churned up by stormwater discharges that scoured sediment into the water column.

Veenstra and Nolen (1991) also noted that sediment can play an important role in the rate of oxygen depletion in the water column by providing oxygen demand from recalcitrant compounds (e.g., iron, manganese, ammonia, sulfides, etc.) as well as particulate organic matter (e.g., algae, bacteria, debris, etc.) and other sources of organic matter that decompose and oxidize. Buhl (2005) reported chemical oxygen demand in sediment collected from a stormwater inlet at 2100 mg/kg (wet weight) and in sediment from the MRG at 760 mg/kg (wet weight). Sources of SOD can include erosion from stream banks and sediment resuspended with increased flow (Fillos and Molof 1972; Kreutzberger et al. 1980; Wang 1980; Walker and Snodgrass 1986, Caldwell and Doyle 1995). Precipitation events of sufficient intensity can result in increased turbidity and increased input of SOD and other oxygen demanding substances (Huggins and Anderson 2005). In the MRG, increased velocity and scouring can disturb or smother sessile organisms (algae, bacteria, some invertebrates; SWCA Environmental Consultants 2007), and increase turbidity, which can shade light levels and reduce algal production (Bixby and Burdett 2009). Other indicators of low DO conditions in the MRG were the high percentage of fly larvae and worms (two year combined average of 81 percent; SWCA Environmental Consultants 2007). Low DO conditions can also release ammonia from organic matter, which can reduce habitat quality for fish and their prey (Merkens and Downing 1957; Fillos and Molof 1972; Thurston et al. 1981; Caldwell and Doyle 1995). Plummer et al. (2004) indicated that groundwater in alluvial sediment below the MRG from Cochiti Reservoir towards La Joya, New Mexico, had DO at 0.5 mg/L. Therefore, groundwater upwelling or erosion of alluvial sediment containing anoxic groundwater could also be sources of low DO in the MRG. SOD appears to be factor in observation of low DO conditions observed in the MRG in this study. However, it is unclear how the variation in water and sediment discharges and SOD inputs are affected by high and low flows, poor land management, flooding, drought, or other activities in the MRG Basin (Graf 1994; Scurlock 1998; Julien et al. 2005; Massong et al. 2007). Moderate to large changes in any one of these factors as a result of a single or multiple events that can affect the oxygen saturation level in the MRG and affect RGSM.

The State of New Mexico dissolved oxygen criterion for this portion of MRG (Segments 20.6.105 and 20.6.106 NMAC) is expressed as mass per volume units (mg/L) in tables based on elevation and temperature (20.6.4.900.N.1). NMED (2009) provided additional criteria guidance based on the instantaneous percent oxygen saturation for warm waters, such as the Rio Grande at a minimum of 75 percent saturation. Using our censored oxygen saturation values, fifteen percent (n=4,394) of our observations at all sites exceed this criterion with 25 percent occurring in summer and 5 percent occurring in winter.

GPP, ER, and PR Ratio

A wide range of ER was observed, and average GPP and PR ratios were generally low. The average PR ratio for sites on the MRG was 0.1, with only 3 sites (Site 1, Site 3, and Site 4) having PR ratios greater than 1 in Year 1, and 2 sites (Site 1 and Site 2) having PR ratios greater than 1 in Year 2. Odum (1956) suggested that rivers with PR ratios less than 1 were heterotrophic and may have little free energy available in organic matter to build large populations of fish and other aquatic organisms. Average PR ratios greater than 1 occurred most during winter (at Sites 1 to 3) when ER was low. On average, ER was five times greater than average GPP, suggesting that the major sources of carbon in the MRG likely come from terrestrial plants in the watershed and not from aquatic plants.

Duffer and Dorris (1966) reported that ER exceeded GPP in a sandbed river in Oklahoma and suggested that the substrate provided less opportunity for benthic producers. Houser et al. (2005) identified that watershed disturbance (i.e., erosion) as negatively affecting ER but not GPP. It is possible that sites with fine sediment are less stable than those with coarse sediment and are more easily mobilized along the bottom and suspended in the water column. Algae associated with sediment can be physically scoured, often damaged and are transported downstream, thus limiting algal growth and production at a particular stream site or reach. Sharp changes in discharge and velocity may have directly or indirectly affected DO, GPP and ER rates, and PR ratios in the MRG, thereby reducing its potential productivity and subsequently its populations of fish, including RGSM.

Summary

The most common degraded water quality condition in the MRG was low oxygen content, likely associated with oxygen demand in sediment. Increasing primary productivity and thereby increasing oxygen saturation could decrease oxygen demand and therefore, ER. Increased oxygen and GPP (e.g., through enhancement of productive aquatic habitats), and reduced SOD (e.g., through erosion control measures) would likely result in increased fish growth and distribution, increased species richness of benthic invertebrates (Odum 1956; Hynes 1970; Davis 1975; Breitburg 1992; Barfour 2000; USEPA 1995, 2010), and decreased chronic stress reported in RGSM (Sykes 2003; Abeyta and Lusk 2004a; Papoulias et al. 2009; Davis and Lusk 2012).

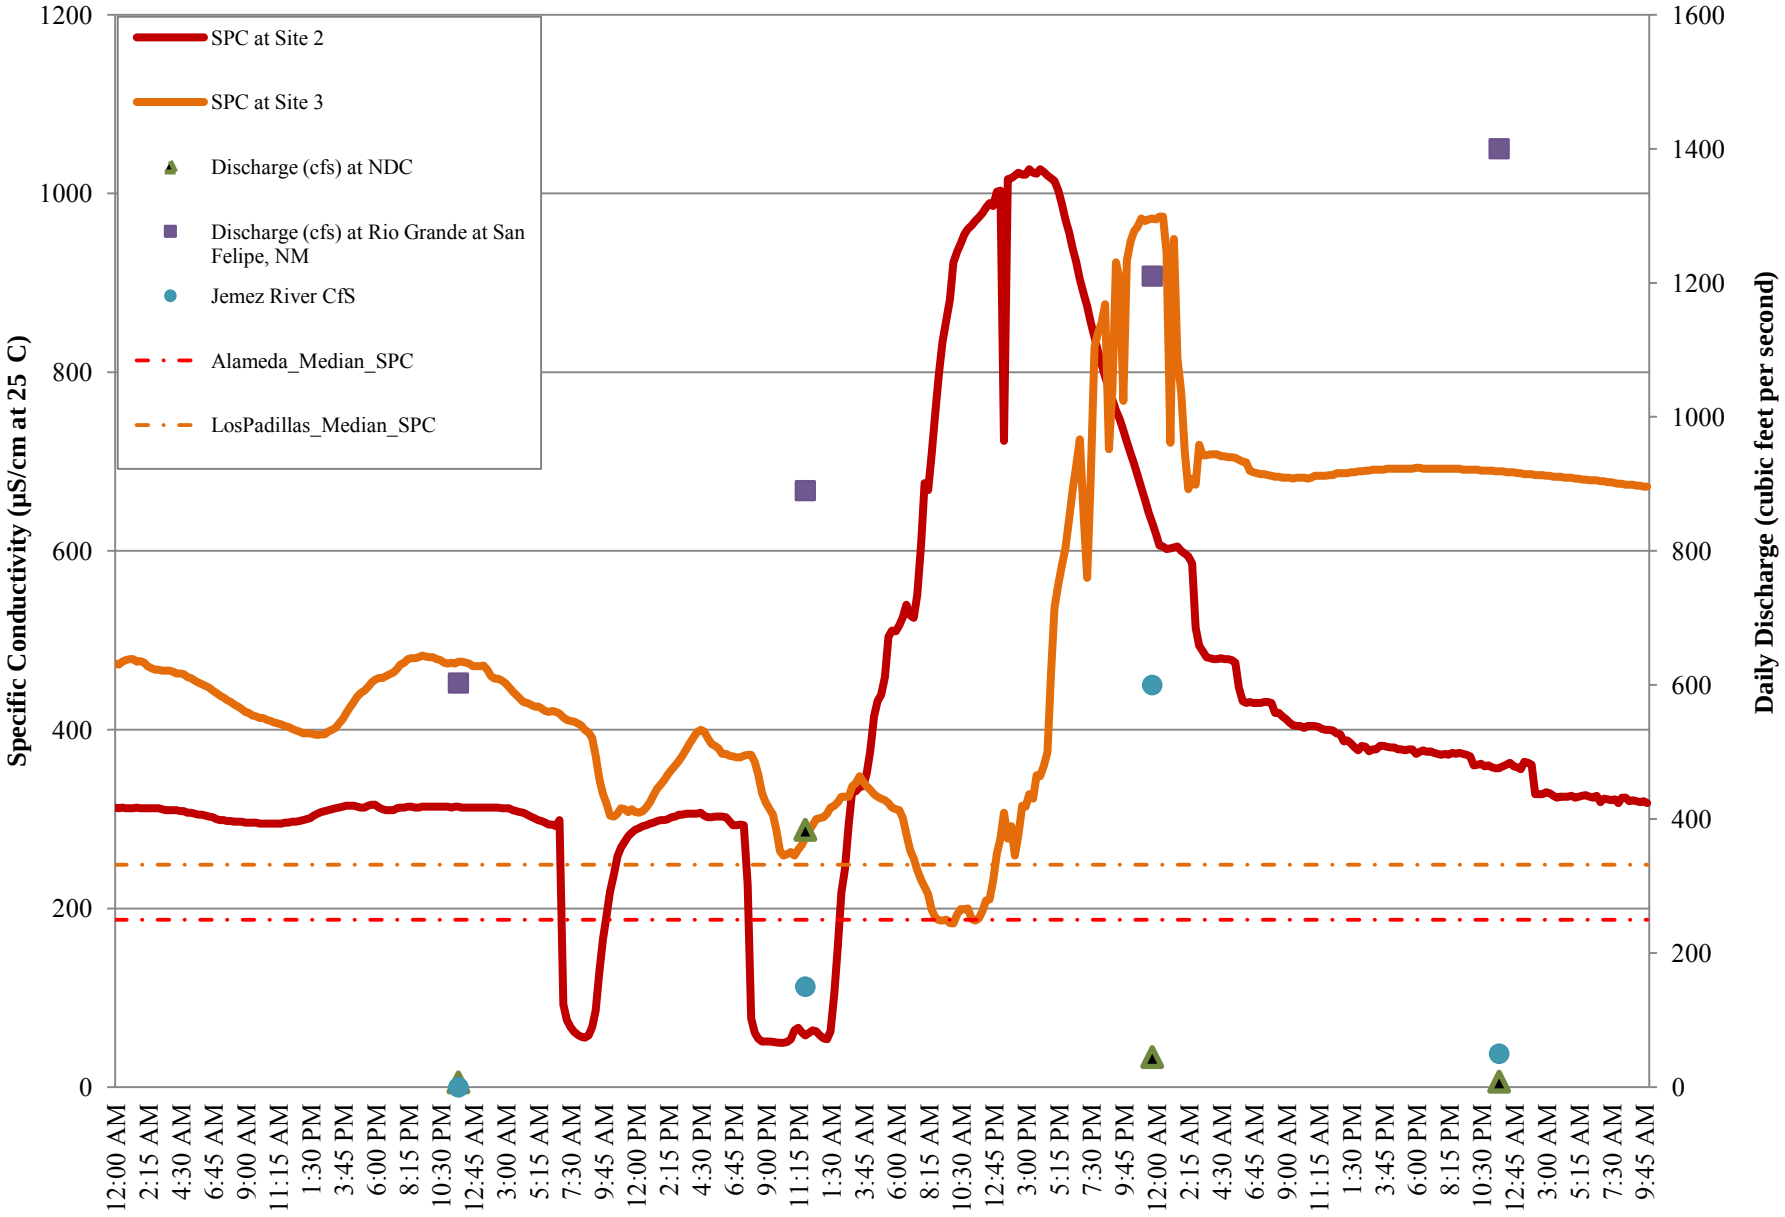

Figure 49. Specific conductivity (SPC; uS/cm at 25C) in the Rio Grande at Site 2 and at Site 3, beginning 12:00AM, October 9, 2006, and Daily Discharge (cubic feet per second (cfs)) at USGS Gage 08329900 (NDC), USGS Gage 08329000 (Jemez River), and USGS Gage 08319000 Rio Grande at San Felipe, New Mexico.

Table 1. Site number, site name name, latitude and longitude (in decimal degress) of a central point, and description of the RGSM Health Study sampling sites.

Site Number	Site Name	Latitude and Longitude (central point - decimal degrees)	Site Location Description
1	Rio Grande at Bernalillo, New Mexico	35.3181, -106.5589	approximately 0.1 mi upstream to 0.8 mi downstream of the Highway 550 Bridge crossing
2	Rio Grande at Alameda, New Mexico	35.2101, -106.6172	approximately 0.7 mi upstream and 1.1 mi downstream of AMAFCA North Diversion Channel mouth
3	Rio Grande at Los Padillas, New Mexico	34.9716, -106.6897	Just north of the Interstate 25 Bridge to approximately 5 mi upstream
4	Rio Grande at Los Lunas, New Mexico	34.8228, -106.7149	approximately 0.6 mi to 2.4 mi north of the Main Street (Highway 6) Bridge crossing
5	Rio Grande at La Joya, New Mexico	34.3073, -106.8493	approximately 2.4 mi to 3.8 mi north of the confluence with the Rio Salado
6	Rio Grande near San Antonio, New Mexico	33.8775, -106.8495	approximately 0.5 mi downstream and 1.2 mi upstream of Bosque del Apache National Wildlife Refuge (BdANWR) North Boundary

Table 5.1. Water quality measurements at Site 1, Rio Grande at Bernalillo, New Mexico, during July 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS		
Report generated:	7/31/2007	11:15:46	
Report from file:	...\SN45473 2006-07-17 130000 Site4-7-17-06.bin		
Win-Situ Version		4.55.3.0	
Serial number:		45473	
Firmware Version		1.58	
Unit name:		Nike	
Barometric Pressure:	636.501	mmHg	
Test defined on:	7/17/2006	2:09:02	
Test scheduled for:	7/17/2006	13:00:00	
Test started on:	7/17/2006	13:00:00	
Test stopped on:	7/31/2006	15:30:09	
Data gathered using linear testing			
Time between data points	900	seconds	
Number of data samples:	944		

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Report from file:	...\SN45475 2006-07-17 130000 Site5-7-17-06.bin		
Win-Situ Version			4.55.3.0
Serial number:			45475
Firmware Version			1.58
Unit name:			Athena
Barometric Pressure:			636.104
Test defined on:		7/17/2006	1:48:14
Test scheduled for:		7/17/2006	13:00:00
Test started on:		7/17/2006	13:00:00
Test stopped on:		7/31/2006	15:25:58
Data gathered using linear testing			
Time between data points		900	seconds
Number of data samples:		943	

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)
7/21/2006	16:45:00	28.7	6.06	94.4

Table 5.2. Water quality measurements at Site 2, Rio Grande at Alameda, New Mexico, during July 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

Table 5.3. Water quality measurements at Site 3, Rio Grande at Los Padillas, New Mexico, during July 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; **, probe improperly deployed, oxygen data inaccurate; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS		
Report generated:		39294.00	11:23:18
Report from file:	...\SN45476 2006-07-17 130000 Site6-7-17-06.bin		
Win-Situ Version	4.55.3.0		
Serial number:		45476.00	
Firmware Version		1.58	
Unit name:	Troll 9000		apollo
Barometric Pressure:		636.71	
Test defined on:		38915.00	1:21:32
Test scheduled for:		38915.00	13:00:00
Test started on:		38915.00	13:00:00
Test stopped on:		38929.00	15:18:09
Data gathered using linear testing			
Time between data points			
Number of data samples:		1354.00	

PROBE MOUNTED BACKWARDS in TUBE - therefore oxygen measurements are unreliable

Table 5.4. Water quality measurements at Site 4, Rio Grande at Los Lunas, New Mexico, during July 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:15:46
Report from file:	...\SN45473 2006-07-17 130000 Site4-7-17-06.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45473	
Firmware Version	1.58	
Unit name:	Troll 9000	nike
Barometric Pressure:	636.501	
Test defined on:	7/17/2006	2:09:02
Test scheduled for:	7/17/2006	13:00:00
Test started on:	7/17/2006	13:00:00
Test stopped on:	7/31/2006	15:30:09
Data gathered using linear testing		
Time between data points	900	
Number of data samples:	365	

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:19:53
Report from file:	...\SN45475 2006-07-17 130000 Site5-7-17-06.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45475	
Firmware Version	1.58	
Unit name:	Troll 9000	athena
Barometric Pressure:		636.104
Test defined on:	7/17/2006	1:48:14
Test scheduled for:	7/17/2006	13:00:00
Test started on:	7/17/2006	13:00:00
Test stopped on:	7/31/2006	15:25:58
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		374

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:23:18
Report from file:	...\SN45476 2006-07-17 130000 Site6-7-17-06.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45476	
Firmware Version	1.58	
Unit name:	Troll 9000	apollo
Barometric Pressure:		636.711
Test defined on:	7/17/2006	1:21:32
Test scheduled for:	7/17/2006	13:00:00
Test started on:	7/17/2006	13:00:00
Test stopped on:	7/31/2006	15:18:09
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		370

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Table 5.7. Water quality measurements at Site 1, Rio Grande at Bernalillo, New Mexico, during October 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:20:36
Report from file:	...\SN45475 2006-10-06 140000 ite1_10_6_06.bin	
Win-Situ Version		4.55.3.0
Serial number:		45475
Firmware Version		1.58
Unit name:		Athena
Barometric Pressure:	636.032	mm Hg
Test defined on:	10/6/2006	13:28:39
Test scheduled for:	10/6/2006	14:00:00
Test started on:	10/6/2006	14:00:00
Test stopped on:	10/13/2006	14:41:42
Data gathered using linear testing		
Time between data points	900	seconds
Number of data samples:	654	

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Power	loss	from	100806	121500	to	101306

Table 5.9. Water quality measurements at Site 2, Rio Grande at Alameda, New Mexico, during October 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:16:48
Report from file:	...\SN45473 2006-10-06 160000 site2_10_6_06.bin	
Win-Situ Version		4.55.3.0
Serial number:		45473
Firmware Version		1.58
Unit name:		Nike
Barometric Pressure:	636.383	mmHg
Test defined on:	10/6/2006	15:13:40
Test scheduled for:	10/6/2006	16:00:00
Test started on:	10/6/2006	16:00:00
Test stopped on:	10/12/2006	15:24:35
Data gathered using linear testing		
Time between data points	900	seconds
Number of data samples:	549	

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS			
Report generated:	7/31/2007	11:23:51		
Report from file:	...\SN45476 2006-10-06 100000 S3-10-6-06.bin			
Win-Situ Version	4.55.3.0			
Serial number:	45476			
Firmware Version	1.58			
Unit name:	Apollo			
Barometric Pressure:	635.805			
Test defined on:	10/5/2006	16:15:06		
Test scheduled for:	10/6/2006	10:00:00		
Test started on:	10/6/2006	10:00:00		
Test stopped on:	10/13/2006	13:32:08		
Data gathered using linear testing				
Time between data points		900	seconds	
Number of data samples:		677		

Date (DDMMYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Table 5.13. Water quality measurements at Site 3, Rio Grande at Los Lunas, New Mexico, during October 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

Table 5.15. Water quality measurements at Site 4, Rio Grande at Los Lunas, New Mexico, during October 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:17:33
Report from file:	...\SN45473 2006-10-13 120000 S4Lunas10_13_06.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45473	
Firmware Version	1.58	
Unit name:	Nike	
Barometric Pressure:	631.587	
Test defined on:	10/12/2006	15:44:10
Test scheduled for:	10/13/2006	12:00:00
Test started on:	10/13/2006	12:00:00
Test stopped on:	1/21/2007	18:22:55
Data gathered using linear testing		
Time between data points	900	Seconds.

Table 5.17. Water quality measurements at Site 5, Rio Grande at La Joya, New Mexico, during October 2006. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	Troll 9000 LTS		
Report generated:	7/31/2007	11:21:26	
Report from file:	...\SN45475 2006-10-13 180000 s5lajoya10_13_06.bin		
Win-Situ Version	4.55.3.0		
Serial number:	45475		
Firmware Version	1.58		
Unit name:	Athena		
Barometric Pressure:		633.624	
Test defined on:	10/13/2006	15:13:13	
Test scheduled for:	10/13/2006	18:00:00	
Test started on:	10/13/2006	18:00:00	
Test stopped on:		abend	
Data gathered using linear testing			
Time between data points		900 seconds	
Number of data samples:		459

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:22:02
Report from file:	...\SN45475 2007-01-22 100000 Site3_1_21_2007.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45475	
Firmware Version	1.58	
Unit name:	Athena	
Barometric Pressure:		629.511
Test defined on:	1/21/2007	17:11:49
Test scheduled for:	1/22/2007	10:00:00
Test started on:	1/22/2007	10:00:00
Test stopped on:	4/13/2007	5:01:47
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		7757

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:22:02
Report from file:	...\SN45475 2007-01-22 100000 Site3_1_21_2007.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45475	
Firmware Version	1.58	
Unit name:	Athena	
Barometric Pressure:		629.511
Test defined on:	1/21/2007	17:11:49
Test scheduled for	1/22/2007	10:00:00
Test started on:	1/22/2007	10:00:00
Test stopped on:	4/13/2007	5:01:47
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		7757

Date (MMDDYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:22:02
Report from file:	...\SN45475 2007-01-22 100000 Site3_1_21_2007.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45475	
Firmware Version	1.58	
Unit name:	Athena	
Barometric Pressure:		629.511
Test defined on:	1/21/2007	17:11:49
Test scheduled for:	1/22/2007	10:00:00
Test started on:	1/22/2007	10:00:00
Test stopped on:	4/13/2007	5:01:47
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		7757

Date (MMDDYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:25:58
Report from file:	...\SN45476 2007-04-13 120000 SIte5_4_13_07.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45476	
Firmware Version	1.58	
Unit name:	Apollo	
Barometric Pressure:		626.12
Test defined on:	2/14/1999	12:47:03
Test scheduled for	4/13/2007	12:00:00
Test started on:	4/13/2007	12:00:00
Test stopped on:	7/16/2007	14:51:58
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		9036

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:22:40
Report from file:	...\SN45475 2007-04-13 150000 Site4_4_13_07lun.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45475	
Firmware Version	1.58	
Unit name:	Athena	
Barometric Pressure:		625.264
Test defined on:	4/13/2007	6:13:15
Test scheduled for:	4/13/2007	15:00:00
Test started on:	4/13/2007	15:00:00
Test stopped on:	7/16/2007	15:36:31
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		9027

Date (MMDDYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

In-Situ Probe:	Troll 9000 LTS	
Report generated:	7/31/2007	11:25:58
Report from file:	...\SN45476 2007-04-13 120000 SIte5_4_13_07.bin	
Win-Situ Version	4.55.3.0	
Serial number:	45476	
Firmware Version	1.58	
Unit name:	Apollo	
Barometric Pressure:		626.12
Test defined on:	2/14/1999	12:47:03
Test scheduled for:	4/13/2007	12:00:00
Test started on:	4/13/2007	12:00:00
Test stopped on:	7/16/2007	14:51:58
Data gathered using linear testing		
Time between data points		900 seconds
Number of data samples:		9036

Date (MMDDYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Table 5.49. Water quality measurements at Site 6, Rio Grande near San Antonio, New Mexico, during October 2007. [Temperature (C), water temperature in Celsius; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]

In-Situ Probe:	**Troll 9000 LTS**	
Report generated:	**3/24/2008**	**11:07:13**
Report from file:	**...\SN45476 2007-10-22 100000 Site6_10_22_07Ap.bin**	
Win-Situ Version	**4.55.3.0**	
Serial number:	**45473**	
Firmware Version	**2**	
Unit name:	**Apollo**	
Barometric Pressure:		**660**
Test defined on:	**10/22/2007**	**9:40:23**
Test scheduled for:	**10/22/2007**	**10:00:00**
Test started on:	**10/22/2007**	**10:00:00**
Test stopped on:	**10/26/2007**	**15:19:54**
Data gathered using linear testing		
Time between data points		**900 seconds**
Number of data samples:		**406**

Date (MMDDYYYY)	Time (HHMMSS)	Temperature (C)	DO (mg/L)	DO Saturation (%)

Table 5.66. Water quality measurements at Site 2, Rio Grande at Alameda, New Mexico, during April 2008. [Temperature (C), water temperature in Celsius; SpCond (uS/cm), specific conductivity in microSiemens per centimeter; pH in standard units; DO (mg/L), dissolved oxygen in milligrams/Liter; DO Saturation (%), percent saturation dissolved oxygen; *, probe likely buried or repositioned; gray shading identifies time between dusk to dawn (see narrative text for more information).]
